Abstract
This paper is a sequel of “Forward Analysis for WSTS, Part I: Completions” [STACS 2009, LIZI
Intl. Proc. in Informatics 3, 433–444] and “Forward Analysis for WSTS, Part II: Complete WSTS”
[Logical Methods in Computer Science 8(3), 2012]. In these two papers, we provided a framework
to conduct forward reachability analyses of WSTS, using finite representations of downwards-
closed sets. We further develop this framework to obtain a generic Karp-Miller algorithm for
the new class of very-WSTS. This allows us to show that coverability sets of very-WSTS can be
computed as their finite ideal decompositions. Under natural assumptions on positive sequences,
we also show that LTL model checking for very-WSTS is decidable. The termination of our
procedure rests on a new notion of acceleration levels, which we study. We characterize those
domains that allow for only finitely many accelerations, based on ordinal ranks.

1 Introduction

Context. A well-structured transition system (WSTS) is an infinite well-quasi-ordered set
of states equipped with transition relations satisfying one of various possible monotonicity
properties. WSTS were introduced in [17] for the purpose of capturing properties common to
a wide range of formal models used in verification. Since their inception, much of the work
on WSTS has been dedicated to identifying generic classes of WSTS for which verification
problems are decidable. Such problems include termination, boundedness [17, 18, 22] and
coverability [1, 2, 7, 8]. In general, verifying safety and liveness properties corresponds
respectively to deciding the coverability and the repeated control-state reachability problems.
Coverability can be decided for WSTS by two different algorithms: the backward algorithm [1,
2] and by combining two forward semi-procedures, one of which enumerates all downwards-
closed invariants [26, 7, 8]. Repeated control-state reachability is undecidable for general
WSTS, but decidable for Petri nets by use of the Karp-Miller coverability tree [32] and the
detection of positive sequences. That technique fails on well-structured extensions of Petri
nets: generating the Karp-Miller tree does not always terminate on \( \nu \)-Petri nets [39], on reset
Petri nets [12], on transfer Petri nets, on broadcast protocols, and on the depth-bounded
\( \pi \)-calculus [30, 38, 44] which can simulate reset Petri nets. This is perhaps why little research
has been conducted on coverability tree algorithms and model checking of liveness properties
for general WSTS. Nonetheless, some recent Petri nets extensions, e.g. \( \omega \)-Petri nets [25] and
unordered data Petri nets [29], benefit from algorithms in the style of Karp and Miller. Hence,
there is hope of finding a general framework of WSTS with Karp-Miller-like algorithms.

* M. Blondin was supported by the Fonds de recherche du Québec – Nature et technologies (FRQNT).
The Karp-Miller coverability procedure. In 1967, Karp and Miller [32] proposed what is now known as the Karp-Miller coverability tree algorithm, which computes a finite representation (the clover) of the downward closure (the cover) of the reachability set of a Petri net. In 1978, Valk extended the Karp-Miller algorithm to post-self-modifying nets [41], a strict extension of Petri nets. In 1987, the second author proposed a generalization of the Karp-Miller algorithm that applies to a class of finitely branching WSTS with strong-strict monotonicity, and having a WSTS completion in which least upper bounds replace the original Petri nets $\omega$-accelerations [17, 18]. In 2004, Finkel, McKenzie and Picaronny [21] applied the framework of [18] to the construction of Karp-Miller trees for strongly increasing $\omega$-recursive nets, a class generalizing post-self-modifying nets. In 2005, Verma and the third author [43] showed that the construction of Karp-Miller trees can be extended to branching vector addition systems with states. In 2009, the second and the third authors [20] proposed a non-terminating procedure that computes the clover of any complete WSTS; this procedure terminates exactly on so-called cover-flattable systems. Recently, this framework has been used for defining computable accelerations in non-terminating Karp-Miller algorithms for both the depth-bounded $\pi$-calculus [30] and for $\nu$-Petri nets; terminating Karp-Miller trees are obtained for strict subclasses.

Model checking WSTS. In 1994, Esparza [15] showed that model checking the linear time $\mu$-calculus is decidable for Petri nets by using both the Karp-Miller algorithm and a decidability result due to Valk and Jantzen [42] on infinite $T$-continual sequences in Petri nets. LTL is undecidable for Petri net extensions such as lossy channel systems [4] and lossy counter machines [40]. In 1998, Emerson and Namjoshi [13] studied the model checking of liveness properties for complete WSTS, but their procedure is not guaranteed to terminate. In 2004, Kouzmin, Shilov and Sokolov [33] gave a generic computability result for a fragment of the $\mu$-calculus; in 2006 and 2013, Bertrand and Schnoebelen [5, 6] studied fixed points in well-structured regular model checking; both [33] and [6] are concerned with formulas with upwards-closed atomic propositions, and do not subsume LTL. In 2011, Chambart, Finkel and Schmitz [10, 11] showed that LTL is decidable for the recursive class of trace-bounded complete WSTS; a class which does not contain all Petri nets.

Our contributions.

- We define very-well-structured transition systems (very-WSTS); a class defined in terms of WSTS completions, and which encompasses models such as Petri nets, $\omega$-Petri nets, post-self-modifying nets and strongly increasing $\omega$-recursive nets. We show that coverability sets of very-WSTS are computable as finite sets of ideals.

- The general clover algorithm of [20], based on the ideal completion studied in [19], does not necessarily terminate and uses an abstract acceleration enumeration. We give an algorithm, the Ideal Karp-Miller algorithm, which organizes accelerations within a tree. We show that this algorithm terminates under natural order-theoretic and effectiveness conditions, which we make explicit. This allows us to unify various versions of Karp-Miller algorithms in particular particular classes of WSTS.

- We identify the crucial notion of acceleration level of an ideal, and relate it to ordinal ranks of sets of reachable states in the completion. We show, notably, that termination is equivalent to the rank being strictly smaller than $\omega^2$. This classifies WSTS into those with high rank (the bad ones), among which those whose sets of states consist of words (e.g., lossy channel systems) or multisets; and those with low rank (the good ones), among which Petri nets and post-self-modifying nets.

- We show that the downward closure of the trace language of a very-WSTS is computable, again as a finite union of ideals. This shows that downward traces inclusion is decidable.
Finally, we prove the decidability of model checking liveness properties for very-WSTS under some effectiveness hypotheses.

**Differences between very-WSTS and WSTS of [18].** The class of WSTS of [18, Def. 4.17] is reminiscent of very-WSTS. It requires WSTS to be finitely branching and strictly monotone, whereas our definition allows infinite branching and requires the completion to be strictly monotone. Moreover, [18, Thm. 4.18], which claims that its Karp-Miller procedure terminates, is incorrect since it does not terminate on transfer Petri nets and broadcast protocols [16], which are finitely branching and strictly monotone WSTS. Finally, some assumptions required to make the Karp-Miller procedure of [18] effective are missing.

Due to space constraints, some proofs are deferred to an extended version of this paper freely available online under the same title.

## 2 Preliminaries

We write $\subseteq$ for set inclusion and $\subset$ for strict set inclusion. A relation $\leq \subseteq X \times X$ over a set $X$ is a **quasi-ordering** if it is reflexive and transitive, and a **partial ordering** if it is antisymmetric as well. It is **well-founded** if it has no infinite descending chain. A quasi-ordering $\leq$ is a **well-quasi-ordering** (resp. well partial order), *wqo* (resp. *wpo*) for short, if for every infinite sequence $x_0, x_1, \ldots \in X$, there exist $i < j$ such that $x_i \leq x_j$. This is strictly stronger than being well-founded.

One example of well-quasi-ordering is the componentwise ordering of tuples over $\mathbb{N}$. More formally, $\mathbb{N}^d$ is well-quasi-ordered by $\leq$ where, for every $x, y \in \mathbb{N}^d$, $x \leq y$ if and only if $x(i) \leq y(i)$ for every $i \in [d]$. We extend $\mathbb{N}$ to $\mathbb{N}_\omega \overset{def}{=} \mathbb{N} \cup \{\omega\}$ where $n \leq \omega$ for every $n \in \mathbb{N}_\omega$. $\mathbb{N}^d_\omega$ ordered componentwise is also well-quasi-ordered. Let $\Sigma$ be a finite alphabet. We denote the set of finite words and infinite words over $\Sigma$ respectively by $\Sigma^*$ and $\omega\Sigma^*$. For every $u, v \in \Sigma^*$, we write $u \preceq v$ if $u$ is a subword of $v$, i.e. $u$ can be obtained from $v$ by removing zero, one or multiple letters. $\Sigma^*$ is well-quasi-ordered by $\preceq$.

**Transition systems.** A (labeled and ordered) transition system is a triple $\mathcal{S} = (X, \Sigma, \preceq)$ such that $X$ is a set, $\Sigma$ is a finite alphabet, $\preceq \subseteq X \times X$ for every $a \in \Sigma$, and $\preceq$ is a quasi-ordering on $X$. Elements of $X$ are called the states of $\mathcal{S}$, each $a \rightarrow x$ is a transition relation of $\mathcal{S}$, and $\preceq$ is the ordering of $\mathcal{S}$. A class $\mathcal{C}$ of transition systems is any set of transition systems. We extend transition relations to sequences over $\Sigma$, i.e. for every $x, y \in X$, $x \rightarrow y$, and $x \rightarrow^\omega y$ if there exists $x' \in X$ such that $x \rightarrow^\omega x'$ and $x' \rightarrow y$. We write $x \rightarrow y$ (resp. $x \rightarrow^\omega y$) if there exists $w \in \Sigma^*$ (resp. $w \in \omega\Sigma^*$) such that $x \rightarrow^w y$. The finite and infinite traces of a transition system $\mathcal{S}$ from a state $x \in X$ are respectively defined as $\text{Traces}_\mathcal{S}(x) \overset{def}{=} \{w \in \Sigma^* : x \rightarrow^w y \text{ for some } y \in X\}$ and $\omega\text{-Traces}_\mathcal{S}(x) \overset{def}{=} \{w \in \omega\Sigma^* : x \rightarrow^w x_1 \rightarrow^w \cdots \text{ for some } x_1, x_2, \ldots \in X\}$.

We define the immediate successors and immediate predecessors of a state $x$ under some sequence $w \in \Sigma^*$ as $\text{Post}_\mathcal{S}(x, w) \overset{def}{=} \{y \in X : x \rightarrow^w y\}$ and $\text{Pre}_\mathcal{S}(x, w) \overset{def}{=} \{y \in X : y \rightarrow^w x\}$. The successors and predecessors of $x \in X$ are $\text{Post}_\mathcal{S}(x) \overset{def}{=} \{y \in X : x \rightarrow y\}$ and $\text{Pre}_\mathcal{S}(x) \overset{def}{=} \{y \in X : y \rightarrow x\}$. These notations are naturally extended to sets, e.g. $\text{Post}_\mathcal{S}(A, w) \overset{def}{=} \{\text{Post}_\mathcal{S}(x, w) : x \in A\}$. We say that $\mathcal{S}$ is deterministic if $|\text{Post}_\mathcal{S}(x, a)| \leq 1$ for every $x \in X$ and $a \in \Sigma$. When $\mathcal{S}$ is deterministic, each $a \in \Sigma$ induces a partial function $t_a : X \rightarrow X$ such that $t_a(x) = y$ for each $x \in X$ such that $\text{Post}_\mathcal{S}(x, a) = \{y\}$. For readability, we simply write $a$ for $t_a$, i.e. $a(x) = t_a(x)$. For every $w \in \Sigma^*$, we write $w(x)$ for $\text{Post}_\mathcal{S}(x, w)$ if $\text{Post}_\mathcal{S}(x, w) \neq \emptyset$.

**Well-structured transition systems.** A (labeled and ordered) transition system $\mathcal{S} = (X, \Sigma, \preceq)$ is a well-structured transition system (WSTS) if $\preceq$ is a well-quasi-ordering and
Forward Analysis for WSTS, Part III: Karp-Miller Trees

\( S \) is monotone, i.e. for all \( x, x', y \in X \) and \( a \in \Sigma \) such that \( x \xrightarrow{a} y \) and \( x' \geq x \), there exists \( y' \in X \) such that \( x' \xrightarrow{a} y' \) and \( y' \geq y \). Many other types of monotonics were defined in the literature (see [22]), but, for our purposes, we only need to introduce strong monotonics. We say that \( S \) has strong monotonicity if for all \( x, x', y \in X \) and \( a \in \Sigma \), \( x \xrightarrow{a} y \) and \( x' > x \) implies \( x' \xrightarrow{a} y' \) for some \( y' \geq y \). We say that \( S \) has strong-strict monotonicity\(^1\) if it has strong monotonicity and for all \( x, x', y \in X \) and \( a \in \Sigma \), \( x \xrightarrow{a} y \) and \( x' > x \) implies \( x' \xrightarrow{a} y' \) for some \( y' > y \).

Verification problems. We say that a target state \( y \in X \) is coverable from an initial state \( x \in X \) if there exists \( z \geq y \) such that \( x \xrightarrow{} z \) and \( z \geq y \). The coverability problem asks whether a target state \( y \) is coverable from an initial state \( x \). The repeated coverability problem asks whether a target state \( y \) is coverable infinitely often from an initial state \( x \); i.e. whether there exist \( z_0, z_1, \ldots \in X \) such that \( x \xrightarrow{\omega} z_0 \xrightarrow{\omega} z_1 \xrightarrow{\omega} \cdots \) and \( z_i \geq y \) for every \( i \in \mathbb{N} \).

3 An investigation of the Karp-Miller algorithm

In order to present our Karp-Miller algorithm for WSTS, we first highlight the key components of the Karp-Miller algorithm for vector addition systems. A \( d \)-dimensional vector addition system (\( d \)-VAS) is a WSTS \( \mathcal{V} = (\mathbb{N}_d, \Sigma, \leq) \) induced by a finite set \( T \subseteq 2^d \) and the rules:

\[
\gamma t \rightarrow y \overset{\text{def}}{=} y = x + t, \text{ for all } x, y \in \mathbb{N}^d, t \in T.
\]

Vector addition systems are deterministic and have strong-strict monotonicity. Given a \( d \)-VAS and a vector \( x_{\text{init}} \in \mathbb{N}_d \), the Karp-Miller algorithm initializes a rooted tree whose root is labeled by \( x_{\text{init}} \). For every \( t \in T \) such that \( x + t \geq 0 \), a child labeled by \( x + t \) is added to the root. This process is repeated successively to the new nodes. If a newly added node \( c : x \) has an ancestor \( c' : x' \) such \( x = x' \), then it is not explored furthermore. If a newly added node \( c : x \) has an ancestor \( c' : x' \) such \( x > x' \), then \( c \) is relabeled by the vector \( y \in \mathbb{N}_d \) such that \( y(i) \overset{\text{def}}{=} x(i) \) if \( x(i) = x'(i) \) and \( y(i) \overset{\text{def}}{=} \omega \) if \( x(i) > x'(i) \). The latter operation is called an acceleration of \( c \).

A vector \( x_{\text{tgt}} \) is coverable from \( x_{\text{init}} \) if and only if the resulting tree \( \mathcal{T} \) contains a node \( c : x \) such that \( x \geq x_{\text{tgt}} \). Similarly, \( x_{\text{tgt}} \) is repeatedly coverable from \( x_{\text{init}} \) if and only if \( \mathcal{T} \) contains a node \( c : x \) that has an ancestor that was accelerated, and such that \( x \geq x_{\text{tgt}} \).

3.1 Ideals and completions

One feature of the Karp-Miller algorithm is that it works over \( \mathbb{N}_d \) instead of \( \mathbb{N}^d \). Intuitively, vectors containing some \( \omega \) correspond to “limit” elements. For a generic WSTS \( S = (X, \Sigma, \leq) \), a similar extension of \( X \) is not obvious. Let us present one, called the completion of \( S \) in [20]. Instead of operating over \( X \), the completion of \( S \) operates over the so-called ideals of \( X \). In particular, the ideals of \( \mathbb{N}^d \) are isomorphic to \( \mathbb{N}_d \).

Let \( X \) be a set quasi-ordered by \( \leq \). The downward closure of \( D \subseteq X \) is defined as \( \downarrow D \overset{\text{def}}{=} \{ x \in X : x \leq y \text{ for some } y \in D \} \). A subset \( D \subseteq X \) is downwards-closed if \( D = \downarrow D \). An ideal is a downwards-closed subset \( I \subseteq X \) that is additionally directed: \( I \) is non-empty and for all \( x, y \in I \), there exists \( z \in I \) such that \( x \leq z \) and \( y \leq z \) (equivalently, every finite subset of \( I \) has an upper bound in \( I \)). We denote the set of ideals of \( X \) by \( \text{Idl}(X) \), i.e. \( \text{Idl}(X) \overset{\text{def}}{=} \{ D \subseteq X : D = \downarrow D \text{ and } D \text{ is directed} \} \).

\(^1\) Strong-strict monotonicity should not be confused with strong and strict monotonics. Here strongness and strictness have to hold at the same time.
It is known that \( \text{Idl}(\mathbb{N}^d) = \{ A_1 \times \cdots \times A_d : A_1, \ldots, A_d \in \{ \downarrow n : n \in \mathbb{N} \} \cup \{ \mathbb{N} \} \} \). Therefore, every ideal of \( \mathbb{N}^d \) is naturally represented by some vector of \( \mathbb{N}^d \), and vice versa. We write \( \omega\text{-rep}(I) \) for this representation, for every \( I \in \text{Idl}(\mathbb{N}^d) \). For example, the ideal \( I = \mathbb{N} \times \downarrow 8 \times \downarrow 3 \times \mathbb{N} \) is represented by \( \omega\text{-rep}(I) = (\omega, 8, 3, \omega) \).

Downwards-closed subsets can often be represented by finitely many ideals:

\[ \text{Theorem 1} \quad ([14, 9, 36, 37, 24, 34]) \quad \text{Let } X \text{ be a well-quasi-ordered set. For every downwards-closed subset } D \subseteq X, \text{ there exist } I_1, I_2, \ldots, I_n \in \text{Idl}(X) \text{ s.t. } D = I_1 \cup I_2 \cup \cdots \cup I_n. \]

This theorem gives rise to a canonical decomposition of downwards-closed sets. The \emph{ideal decomposition} of a downwards-closed subset \( D \subseteq X \) is the set of maximal ideals contained in \( D \) with respect to inclusion. We denote the ideal decomposition of \( D \) by \( \text{IdealDecomp}(D) \overset{\text{def}}{=} \max \subseteq \{ I \in \text{Idl}(X) : I \subseteq D \} \). By Theorem 1, \( \text{IdealDecomp}(D) \) is finite, and \( D = \bigcup_{I \in \text{IdealDecomp}(D)} I \). In [20, 7], the notion of ideal decomposition is used to define the completion of unlabeled WSTS. We slightly extend this notion to labeled WSTS:

\[ \text{Definition 2} \quad \text{Let } S = (X, \rightarrow, \leq) \text{ be a labeled WSTS. The completion of } S \text{ is the labeled transition system } \hat{S} = (\text{Idl}(X), \rightarrow, \leq) \text{ such that } I \rightarrow J \text{ if, and only if,} J \in \text{IdealDecomp}(\downarrow \text{Post}_S(I, a)). \]

The completion of a WSTS enjoys numerous properties. In particular, it has strong monotonicity, and it is finitely branching [7], i.e. \( \text{Post}_S(I, a) \) is finite for every \( I \in \text{Idl}(X) \) and \( a \in \Sigma \). Note that if \( S \) has strong-strict monotonicity, then this property is not necessarily preserved by \( \hat{S} \) [7]. Moreover, the completion of a WSTS may not be a WSTS since \( \text{Idl}(X) \) is not always well-quasi-ordered by \( \subseteq \). However, for the vast majority of models used in verification, \( \text{Idl}(X) \) is well-quasi-ordered, and hence completions remain well-structured. Indeed, \( \text{Idl}(X) \) is well-quasi-ordered if and only if \( X \) is a so-called \( \omega^2 \)-wqo, and all known wqos, except possibly graphs under minor embedding, are \( \omega^2 \)-wqo, as discussed in [20]. The traces of a WSTS are closely related to those of its completion:

\[ \text{Proposition 3} \quad ([7]) \quad \text{The following holds for every WSTS } S = (X, \rightarrow, \leq): \]

1. For all \( x, y \in X \) and \( w \in \Sigma^* \), if \( x \xrightarrow{w} y \), then for every ideal \( I \supseteq \downarrow x \), there exists an ideal \( J \supseteq \downarrow y \) such that \( I \xrightarrow{w} J \).
2. For all \( I, J \in \text{Idl}(X) \) and \( w \in \Sigma^* \), if \( I \xrightarrow{w} J \), then for every \( y \in J \), there exist \( x \in I, y' \in X \) and \( w' \in \Sigma^* \) such that \( x \xrightarrow{w'} y' \) and \( y' \geq y \). If \( S \) has strong monotonicity, then \( w' = w \).
3. If \( S \) has strong monotonicity, then \( \bigcup_{J \in \text{Post}_S(I, w)} J = \downarrow \text{Post}_S(I, w) \) for all \( I \in \text{Idl}(X) \) and \( w \in \Sigma^* \).
4. If \( S \) has strong monotonicity, then \( \text{Traces}_S(x) = \text{Traces}_S(\downarrow x) \) and \( \omega\text{-Traces}_S(x) \subseteq \omega\text{-Traces}_S(\downarrow x) \) for every \( x \in X \).

It is worth noting that if \( S \) is infinitely branching, then an infinite trace of \( \hat{S} \) from \( \downarrow x \) is not necessarily an infinite trace of \( S \) from \( x \) (e.g. see [7]). Whenever the completion of a WSTS \( S \) is deterministic, we will often write \( w(I) \) for \( \text{Post}_S(I, w) \) if the latter is nonempty and if there is no ambiguity with \( \text{Post}_S(I, w) \).

### 3.2 Levels of ideals

The Karp-Miller algorithm terminates for the following reasons: \( \mathbb{N}^d \) is well-quasi-ordered and \( \omega \)'s can only be added to vectors along a branch at most \( d \) times. Loosely speaking, the latter property means that \( \text{Idl}(\mathbb{N}^d) \) has \( d + 1 \) “levels”. Here, we generalize this notion.
We say that an infinite sequence of ideals $I_0, I_1, \ldots \in \text{Idl}(X)$ is an acceleration candidate if $I_0 \subset I_1 \subset \cdots$.

> **Definition 4.** For every $n \in \mathbb{N}$, the $n^{th}$ level of $\text{Idl}(X)$ is defined as

$$\text{Acc}_n(X) = \begin{cases} \text{Idl}(X) & \text{if } n = 0, \\ \{ \cup_{i \in \mathbb{N}} I : I_0, I_1, \ldots \in \text{Acc}_{n-1}(X) \text{ is an acceleration candidate} \} & \text{if } n > 0. \end{cases}$$

We observe that $\text{Acc}_{n+1}(X) \subseteq \text{Acc}_n(X)$ for every $n \in \mathbb{N}$. Moreover, as expected:

$$\text{Acc}_n(\mathbb{N}^d) = \{ I \in \text{Idl}(\mathbb{N}^d) : \omega\text{-rep}(I) \text{ has at least } n \text{ occurrences of } \omega \}.$$  

We say that $\text{Idl}(X)$ has finitely many levels if there exists $n \in \mathbb{N}$ such that $\text{Acc}_n(X) = \emptyset$. For example, $\text{Acc}_{d+1}(\mathbb{N}^d) = \emptyset$.

### 3.3 Accelerations

The last key aspect of the Karp-Miller algorithm is the possibility to accelerate nodes. In order to generalize this notion, let us briefly develop some intuition. Recall that a newly added node $c : x$ is accelerated if it has an ancestor $c' : x'$ such that $x > x'$. Consider the non-empty sequence $w$ labeling the path from $c'$ to $c$. Since $d$-VAS have strong-strict monotonicity, both over $\mathbb{N}^d$ and $\mathbb{N}_d^d$, $w^n(x)$ is defined for every $n \in \mathbb{N}$. For example, if $(5,0,1) \xrightarrow{w} (5,1,3)$ is encountered, $(5,1,3)$ is replaced by $(5,\omega,\omega)$. This represents the fact that for every $n \in \mathbb{N}$, there exists some reachable marking $y \geq (5,n,n)$. Note that an acceleration increases the number of occurrences of $\omega$. In our example, the ideal $I = \downarrow 5 \times \downarrow 1 \times \downarrow 3$, which is of level 0, is replaced by $I' = \downarrow 5 \times \mathbb{N} \times \mathbb{N}$, which is of level 2. Based on these observations, we extend the notion of acceleration to completions:

> **Definition 5.** Let $\mathcal{S} = (X, \Sigma, \preceq)$ be a WSTS such that $\hat{\mathcal{S}}$ is deterministic and has strong-strict monotonicity, let $w \in \Sigma^*$ and let $I \in \text{Idl}(X)$. The acceleration of $I$ under $w$ is defined as:

$$w^\infty(I) \overset{\text{def}}{=} \begin{cases} \bigcup_{k \in \mathbb{N}} w^k(I) & \text{if } I \subseteq w(I), \\ I & \text{otherwise.} \end{cases}$$

Note that for every ideal $I$, $w^\infty(I)$ is also an ideal. As for $\text{Idl}(\mathbb{N}^d)$, any successor $J$ of an ideal $I$ belongs to the same level of $I$, and accelerating an ideal increases its level.

> **Proposition 6.** Let $\mathcal{S} = (X, \Sigma, \preceq)$ be a WSTS such that $\mathcal{S}$ has strong monotonicity, and $\hat{\mathcal{S}}$ is deterministic and has strong-strict monotonicity. For every $I \in \text{Idl}(X)$ and $w \in \Sigma^*$,

1. if $\text{Post}_\hat{\mathcal{S}}(I,w) \neq \emptyset$ and $I \in \text{Acc}_n(X)$ for some $n \in \mathbb{N}$, then $w(I) \in \text{Acc}_n(X)$;
2. if $I \subseteq w(I)$ and $I \in \text{Acc}_n(X)$ for some $n \in \mathbb{N}$, then $w^\infty(I) \in \text{Acc}_{n+1}(X)$.

### 4 The Ideal Karp-Miller algorithm

We may now present our generalization of the Karp-Miller algorithm. To do so, we first define the class of WSTS that enjoys all of the properties introduced in the previous section:

> **Definition 7.** A very-WSTS is a labeled WSTS $\mathcal{S} = (X, \Sigma, \preceq)$ such that:

- $\mathcal{S}$ has strong monotonicity,
- $\hat{\mathcal{S}}$ is a deterministic WSTS with strong-strict monotonicity,
- $\text{Idl}(X)$ has finitely many levels.
The class of very-WSTS includes vector addition systems, Petri nets, ω-Petri nets [25], post-self-modifying nets [41] and strongly increasing ω-recursive nets [21]. However, very-WSTS do not include transfer Petri nets, since \( \hat{S} \) does not have strict monotonicity, and unordered data Petri nets, since \( \text{Idl}(X) \) has infinitely many levels. Note that \( \hat{S} \) may be deterministic (and finitely branching) even when \( S \) is not, and even when \( S \) is not finitely branching, as the example of ω-Petri nets shows.

We present the Ideal Karp-Miller algorithm (IKM) for this class in Algorithm 4.1. The algorithm starts from an ideal \( I_0 \), successively computes its successors in \( \hat{S} \) and performs accelerations as in the classical Karp-Miller algorithm for VAS. Note that we do not allow for nested accelerations. For every node \( c : (I, n) \) of the tree built by the algorithm, we write ideal\((c)\) for \( I \), and num-accel\((c)\) for \( n \), which will be the number of accelerations made along the branch from the root to \( c \) (inclusively). Let us first show that the algorithm terminates.

**Algorithm 4.1: Ideal Karp-Miller algorithm.**

1. initialize a tree \( T \) with root \( r : (I_0, 0) \)
2. while \( T \) contains an unmarked node \( c : (I, n) \) do
3.   if \( c \) has an ancestor \( c' : (I', n') \) s.t. \( I' = I \) then mark \( c \)
4.   else
5.     if \( c \) has an ancestor \( c' : (I', n') \) s.t. \( I' \subset I \)
6.        and \( n' \!= n \) /* no acceleration occurred between \( c' \) and \( c */ \) then
7.        \( w \leftarrow \) sequence of labels from \( c' \) to \( c \)
8.        replace \( c : (I, n) \) by \( c : \langle w^\infty(I), n + 1 \rangle \)
9.     for \( a \in \Sigma \) do
10.        if \( a(I) \) is defined then
11.           add are labeled by \( a \) from \( c \) to a new child \( d : \langle a(I), n \rangle \)
12.    mark \( c \)
13. return \( T \)

**Theorem 8.** Algorithm 4.1 terminates for very-WSTS.

**Proof.** We note the following invariants: (1) for every node \( c : (I, n) \) of \( T \), \( I \) is in Acc\(_n\)(\( X \)); (2) at line 2, i.e., each time control returns to the beginning of the loop, all unmarked nodes of \( T \) are leaves; (3) num-accel\((c)\) is non-decreasing on each branch of \( T \), that is: for every branch \( c_0 : (I_0, n_0), c_1 : (I_1, n_1), \ldots, c_k : (I_k, n_k) \) of \( T \), we have \( n_1 \leq n_2 \leq \cdots \leq n_k \). (1) is by Proposition 6, (2) is an easy induction on the number of times through the loop, and (3) is also by induction, noticing that by (2) only \( n_k \) can increase when line 8 is executed.

The rest of the argument is as for the classical Karp-Miller algorithm. Suppose the algorithm does not terminate. Let \( T_n \) be the finite tree obtained after \( n \) iterations. The infinite sequence \( T_0, T_1, \ldots \) defines a unique infinite tree \( T_\infty = \bigcup_{n \in \mathbb{N}} T_n \). Since \( \hat{S} \) is finitely branching, \( T_\infty \) is also finitely branching. Therefore, \( T_\infty \) contains an infinite path \( c_0 : (I_0, n_0), c_1 : (I_1, n_1), \ldots, c_k : (I_k, n_k), \ldots \), by König’s lemma. By (1), and since \( \text{Idl}(X) \) has finitely many levels, the numbers \( n_k \) assume only finitely many values. Let \( N \) be the largest of those values. Using (3), there is a \( k_0 \in \mathbb{N} \) such that \( n_k = N \) for every \( k \geq k_0 \). Since \( \hat{S} \) is a WSTS, hence \( \text{Idl}(X) \) is wqo, we can find two indices \( i, j \) with \( k_0 \leq i < j \) and such that \( I_i \subset I_j \). If \( I_i = I_j \), then line 3 of the algorithm would have stopped the exploration of the path. Hence \( I_i \subset I_j \), but then line 8 would have replaced num-accel\((c_j)\) = \( N \) by \( N + 1 \), contradiction. ◀
4.1 Properties of the algorithm

Let $T_I$ denote the tree induced by the set of nodes returned by Algorithm 4.1 on input $(S, I)$. Let $D_I = \bigcup_{c \in T_I} \text{id}(c)$. We claim that $D_I = \downarrow Post_S^*(I)$. Instead of proving this claim directly, we take traces into consideration and prove a stronger statement. We define two word automata that will be useful for this purpose.

Definition 9. The stuttering automaton2 is the finite word automaton $A_I$ obtained by making all of the states of $T_I$ accepting, by taking the root $r$ as the initial state, and by taking the arcs of $T_I$ as transitions, together with the following additional transitions:
- If a leaf $c$ of $T_I$ has an ancestor $c'$ such that $\text{id}(c) = \text{id}(c')$, then a transition from $c$ to $c'$ labeled by $\varepsilon$ is added to $A_I$.

The Karp-Miller automaton is the automaton $K_I$ obtained by extending $A_I$ as follows:
- If a node $c$ of $T_I$ has been accelerated because of an ancestor $c'$, then a transition from $c$ to $c'$ labeled by $\varepsilon$ is added to $K_I$.

Both $A_I$ and $K_I$ can be computed from $T_I$. Moreover, they give precious information about the traces of $S$. Let $L(A_I)$ and $L(K_I)$ denote the language over $\Sigma$ accepted by $A_I$ and $K_I$. We will show the following theorem:

Theorem 10. For every every-WSTS $S = (X, \xrightarrow{} , \leq)$ and $I \in \text{Idl}(X)$,

$$D_I = \downarrow Post_S^*(I), \text{Traces}_S(I) \subseteq L(A_I) \text{ and } L(K_I) \subseteq \downarrow \leq \text{Traces}_S(I).$$

In particular, for every $x \in X$, $D_{I|x} = \downarrow Post_S^*(x)$, $\downarrow \leq L(K_{I|x}) = \downarrow \leq \text{Traces}_S(x)$, and $\downarrow \leq \text{Traces}_S(x)$ is a computable regular language.

The proof of Theorem 10 follows from the forthcoming Prop. 11 describing the relations between traces of $A_I$ and $K_I$ with traces of $S$ and $\bar{S}$. We write $c \xrightarrow{w} c', c \xrightarrow{w} \langle A \rangle c'$ and $c \xrightarrow{w} \langle K \rangle c'$ whenever node $c'$ can be reached by reading $w$ from $c$ in $T_I$, $A_I$ and $K_I$ respectively.

Proposition 11. Let $S = (X, \xrightarrow{} , \leq)$ be a every-WSTS and let $I_0 \in \text{Idl}(X)$.

1. For every $y, z \in X$, $w \in \Sigma^*$ and $c \in A_{I_0}$, if $y \xrightarrow{w} z$ and $y \in \text{id}(c)$, then there exists $d \in A_{I_0}$ such that $c \xrightarrow{w} \langle A \rangle d$ and $z \in \text{id}(d)$.
2. For every $y, z \in X$, $w \in \Sigma^*$ and $c, d \in K_{I_0}$, if $c \xrightarrow{w} \langle K \rangle d$ and $z \in \text{id}(d)$, then there exist $y \in \text{id}(c), w' \geq w$ and $z' \geq z$ such that $y \xrightarrow{w'} z'$.

Proof. We only prove (2). The proof is by induction on $|w|$. If $|w| = 0$, then $w = \varepsilon$. We stress the fact that even though $w$ is empty, $d$ might differ from $c$ since $K_{I_0}$ contains $\varepsilon$-transitions. However, by definition of $K_{I_0}$, we know that $\text{id}(d) \preceq \text{id}(c)$. Therefore, $z \in \text{id}(c)$, and we are done since $z \xrightarrow{\varepsilon} z$.

Suppose that $|w| > 0$. Assume the claim holds for every word of length less than $|w|$. There exist $u, v \in \Sigma^*, a \in \Sigma$ and $d' \in K_{I_0}$ such that $w = uav$, $c \xrightarrow{u} d' \xrightarrow{a} d \xrightarrow{v} \langle K \rangle d$ and $d'$ is the parent of $d$ in $T_{I_0}$. Let $I_0 \equiv \text{id}(c), J \equiv \text{id}(d'), K \equiv \text{id}(d)$, and $K' \equiv a(J)$.

By induction hypothesis, there exist $y_K \in K, v' \geq v$ and $z' \geq z$ such that $y_K \xrightarrow{v'} z'$.

= If $K = K'$, then $J \xrightarrow{a} K$. By definition of $\xrightarrow{a}$, there exist $y_J \in J$ and $y_K \geq y_K$ such that $y_J \xrightarrow{a} y_K$. By induction hypothesis, there exist $y_J \in I, u' \geq u$ and $y_J \geq y_J$ such that $y_J \xrightarrow{u'} y_J$. By strong monotonicity of $S$, there exists $z'' \geq z'$ such that $y_J \xrightarrow{u'v'} z''$. We are done since $u'v' \geq uav$.

2 We use the term stuttering as paths of the automaton correspond to stuttering paths of [25].
If \( K \neq K' \), then \( K \) was obtained through an acceleration. Therefore, \( K = \sigma^\infty(K') \) for some \( \sigma \in \Sigma^* \). This implies that \( y_K \in \sigma^k(K') \) for some \( k \in \mathbb{N} \). Let \( L \equiv \sigma^k(K') \). Note that \( J \xrightarrow{\alpha} K' \xrightarrow{\sigma^k} L \). By Prop. 3(2), there exist \( y_J \in J \) and \( y_K' \geq y_K \) such that \( y_J \xrightarrow{\sigma^k} y_K' \).

By induction hypothesis, there exist \( y_I \in I \), \( u' \geq u \) and \( y_J' \geq y_J \) such that \( y_I \xrightarrow{\alpha} y_J' \). By strong monotonicity of \( S \), there exists \( z'' \geq z' \) such that \( y_I \xrightarrow{\alpha \sigma^k \sigma^k} z'' \). ▶

### 4.2 Effectiveness of the algorithm

The Ideal Karp-Miller algorithm can be implemented provided that (1) ideals can be effectively manipulated, (2) inclusion of ideals can be tested, (3) \( \text{Post}_S(I) \) can be computed for every ideal \( I \), and (4) \( w^\infty(I) \) can be computed for every ideal \( I \) and sequence \( w \). A class of WSTS satisfying (1–3) is called completion-post-effective, and a class satisfying (4) is called \( \infty \)-completion-effective. By Theorem 10, we obtain the following result:

▶ Theorem 12. Let \( C \) be a completion-post-effective and \( \infty \)-completion-effective class of every-WSTS. The ideal decomposition of \( \downarrow \text{Post}_S(x) \) can be computed for every \( S = (X, \rightarrow, \subseteq) \in C \) and \( x \in X \). In particular, coverability for \( C \) is decidable.

### 5 A characterization of acceleration levels

We pause for a moment, and give a precise characterization of ideals that have finitely many levels. We shall then discuss some extensions briefly, beyond the finitely many level case.

Let \( Z \) be a well-founded partially ordered set, abstracting away from the case \( Z = \text{Idl}(X) \). The rank of \( z \in Z \), denoted \( \text{rk} \ z \), is the ordinal defined inductively by \( \text{rk} \ z \equiv \sup \{ \text{rk} \ y + 1 : y < z \} \), where \( \sup(\emptyset) \equiv 0 \). The rank of \( Z \) is defined as \( \text{rk} \ Z \equiv \sup \{ \text{rk} \ z + 1 : z \in Z \} \). We say that a sequence \( z_0, z_1, \ldots \in Z \) is an acceleration candidate if \( z_1 < z_2 < \cdots < z_i < \cdots \). Such an acceleration candidate goes through a set \( A \) if \( z_i \in A \) for some \( i \in \mathbb{N} \), and is below \( z \in Z \) if \( z_i \leq z \) for every \( i \in \mathbb{N} \). We define a family of sets \( A_\alpha(Z) \) closely related to levels of ideals:

▶ Definition 13. Let \( Z \) be a partially ordered set. Let \( A_0(Z) \equiv \emptyset \). For every ordinal \( \alpha > 0 \), \( A_\alpha(Z) \) is the set of elements \( z \in Z \) such that every acceleration candidate below \( z \) goes through \( A_\beta(Z) \) for some ordinal \( \beta < \alpha \).

Observe that \( A_\alpha(Z) \subseteq A_\beta(Z) \) for every \( \alpha \leq \beta \), and that \( A_\alpha(\text{Idl}(X)) \) is the set of \( d \)-tuples with less than \( n \) components equal to \( \omega \). It is easily shown that \( A_\alpha(\text{Idl}(X)) \) is the upward closure of the complement of \( \text{Acc}_\alpha(X) \). Consequently, \( A_\alpha(\text{Idl}(X)) = \text{Idl}(X) \) if and only if \( \text{Acc}_\alpha(X) = \emptyset \), and we can bound levels of \( \text{Idl}(X) \) by means of \( A_\alpha(\text{Idl}(X)) \).

Let us first show that \( A_\alpha(Z) \) is exactly the set of elements of rank less than \( \omega \cdot n \). This rests on the following, which is perhaps less obvious than it seems.

▶ Lemma 14. Let \( Z \) be a countable wpo. For every \( z \in Z \) such that \( \text{rk} \ z \) is a limit ordinal, \( z \) is the supremum of some acceleration candidate \( z_0 < z_1 < \cdots \). Moreover, for any given ordinal \( \beta < \text{rk} \ z \), the acceleration candidate can be chosen such that \( \beta \leq z_i \) for every \( i \in \mathbb{N} \).

This fails if \( Z \) is not countable: take \( Z = \omega_1 + 1 \), where \( \omega_1 \) is the first uncountable ordinal, then \( \omega_1 \in Z \) is not the supremum of countably many ordinals \( < \omega_1 \). This also fails if \( Z \) is not wpo, even when \( Z \) is well-founded: consider the set with one root \( r \) above chains of length \( n \), one for each \( n \in \mathbb{N} \): \( \text{rk} \ r = \omega \), but there is no acceleration candidate below \( r \).

Proof. Let \( \alpha \equiv \text{rk} \ z \). A fundamental sequence for \( \alpha \) is a monotone sequence of ordinals strictly below \( \alpha \) whose supremum equals \( \alpha \). Fundamental sequences exist for all countable limit
ordinals, in particular for $\alpha$, since $Z$ is countable (e.g. see [23]). Pick one such fundamental subsequence $(\gamma_i)_{i \in \mathbb{N}}$. Replacing $\gamma_i$ by $\sup(\beta, \gamma_i)$ if necessary, we may assume that $\beta \leq \gamma_m$ for every $i \in \mathbb{N}$. By the definition of rank, for every $i \in \mathbb{N}$, there is an element $z_i < z$ of rank at least $\gamma_i$. Since $Z$ is well-quasi-ordered, we may extract a non-decreasing subsequence from $(z_i)_{i \in \mathbb{N}}$. Without loss of generality, assume that $z_0 < z_1 < \cdots$. If all but finitely many of these inequalities were equalities, then $z$ would be equal to $z_i$ for $m$ large enough, but that is impossible since $z_i < z$. We can therefore extract a strictly increasing subsequence from $(z_i)_{i \in \mathbb{N}}$. This is an acceleration sequence, its supremum is $z$, and $\beta \leq \gamma_i \leq z_i$ for every $i$.

\[\blacktriangleright\textbf{Lemma 15.} \text{Let } Z \text{ be a countable wpo, and let } n \in \mathbb{N}. \text{ For every } z \in Z, \text{ rk } z < \omega \cdot n \text{ if and only if } z \in A_n(Z). \]

\textbf{Proof.} $\Rightarrow$ By induction on $n$. The case $n = 0$ is immediate. Let $n \geq 1$. Given any acceleration candidate $z_1 < z_2 < \cdots$ below $z$, we must have $\text{rk } z_1 < \text{rk } z_2 < \cdots < \text{rk } z$. Since $\text{rk } z < \omega \cdot n$, there exist $\ell, m \in \mathbb{N}$ with $\ell < n$ such that $\text{rk } z = \omega \cdot \ell + m$. Therefore, $\text{rk } z_i \geq \omega \cdot \ell$ for only finitely many $i$. In particular, there exists some $i$ such that $\text{rk } z_i < \omega \cdot \ell$. Since $\ell < n$, we have $\text{rk } z_i < \omega \cdot (n - 1)$. By induction hypothesis, $z_i \in A_{n-1}(Z)$, and hence $z \in A_n(Z)$.

$\Leftarrow$ We show by induction on $n$ that $\text{rk } z \geq \omega \cdot n$ implies $z \not\in A_n(Z)$. The case $n = 0$ is immediate. Let $n \geq 1$. In general, $\text{rk } z$ is not a limit ordinal, but can be written as $\alpha + \ell$ for some limit ordinal $\alpha$ and some $\ell \in \mathbb{N}$. By definition of rank, $z$ is larger than some element of rank $\alpha + (\ell - 1)$, which is itself larger than some element of rank $\alpha + (\ell - 2)$, and so on. Iterating this way, we find an element $y \leq z$ of rank exactly $\alpha$. Since $y$ is a limit ordinal, $\text{rk } y$ is the supremum of some acceleration candidate $z_0 < z_1 < \cdots$. Moreover, since $\omega \cdot (n - 1) < \text{rk } y$, we may assume that $\text{rk } z_i \geq \omega \cdot (n - 1)$ for every $i \in \mathbb{N}$. By induction hypothesis, $z_i \not\in A_{n-1}(Z)$ for every $i \in \mathbb{N}$, and hence $z \not\in A_n(Z)$.

\[\blacktriangleright\textbf{Theorem 16.} \text{Let } X \text{ be a countable wpo such that Idl}(X) \text{ is well-quasi-ordered by inclusion}\textsuperscript{3}. The following holds: Idl}(X) \text{ has finitely many levels if and only if } \text{rk Idl}(X) < \omega^2. \]

\textbf{Proof.} We apply Lemma 15 to $Z = \text{Idl}(X)$, a wpo by assumption. For that, we need to show that $Z$ is countable. There are countably many upwards-closed subsets, since they are all determined by their finitely many minimal elements. Downwards-closed subsets are in one-to-one correspondence with upwards-closed subsets, through complementation, hence are countably many as well, and ideals are particular downwards-closed subsets.

We conclude by noting that the following are equivalent: (1) $\text{rk Idl}(X) < \omega^2$; (2) $\text{rk Idl}(X) \leq \omega \cdot n$ for some $n \in \mathbb{N}$; (3) $A_n(\text{Idl}(X)) = \text{Idl}(X)$ for some $n \in \mathbb{N}$ (by Lemma 15); (4) $\text{Acc}_n(\emptyset) = \emptyset$ for some $n \in \mathbb{N}$.

While $\text{rk Idl}(\mathbb{N}^d) = \omega \cdot d + 1 < \omega^2$, not all wqos $X$ used in verification satisfy $\text{rk Idl}(X) < \omega^2$. For example, $\text{rk Idl}(\Sigma^*) = \omega^{1+1}$, for any finite alphabet $\Sigma$; a similar result holds for multisets over $\Sigma$.

Note that the IKM algorithm still terminates if, for each branch $B = (c_0 : (I_0, n_0), c_1 : (I_1, n_1), \ldots, c_k : (I_k, n_k), \ldots)$ of the Ideal Karp-Miller tree, $[B] \overset{d}{=} \{ I \in \text{Idl}(X) : \exists j, k \in \mathbb{N}, j \leq k \text{ and } I_j \subseteq I \subseteq I_k \}$ has rank less than $\omega^2$. Indeed, the IKM algorithm terminates if and only if each branch $B$ is finite, and the states involved in computing the branch, as well as all needed accelerations, are all included in $[B]$. Therefore, relaxing “$\text{rk Idl}(X) < \omega^2$” to the more technical condition “$\text{rk } [B] < \omega^2$” may allow one to extend the notion of very-WSTS.

\textsuperscript{3} Recall that such a wqo is known as an $\omega^2$-wqo [20]. That we find the ordinal $\omega^2$ in the statement of Theorem 16 and in the notion of $\omega^2$-wqo seems to be coincidental.
6 Model checking liveness properties for very-WSTS

In this section, we show how the Ideal Karp-Miller algorithm can be used to test whether a very-WSTS violates a liveness property specified by an LTL formula. Testing that $S$ violates a property $\varphi$ amounts to constructing a Büchi automaton $B_{\neg\varphi}$ for $\neg\varphi$ and to test whether $B_{\neg\varphi}$ accepts an infinite trace of $S$. We first introduce positive very-WSTS, and show that repeated coverability is decidable for them under some effectiveness hypothesis. Then, we show how LTL model checking for positive very-WSTS reduces to repeated coverability.

6.1 Deciding repeated coverability

Let $S = (X, \Sigma, \to, \leq)$ be a WSTS and let $x \in X$. We say that $w \in \Sigma^*$ is positive for $x$ if there exists some $y \in X$ such that $x \to^w y$ and $x \leq y$. We say that $w \in \Sigma^*$ is positive if $w$ is positive for every $x \in X$ such that $Post(x, w) \neq \emptyset$. We say that a WSTS $S = (X, \Sigma, \to, \leq)$ is positive if for every $w \in \Sigma^*$, $w$ is positive for some $x \in X$ if and only if $w$ is positive.

We establish a necessary and sufficient condition for repeated coverability in terms of the stuttering automaton and positive sequences:

\begin{proposition}
Let $S = (X, \Sigma, \to, \leq)$ be a positive very-WSTS, and let $x, y \in X$. State $y$ is repeatedly coverable from $x$ if and only if there are states $c, d$ of the stuttering automaton $A_{\lx}$ and $w \in \Sigma^+$ such that $c \xrightarrow{w \cdot A} d$, $\text{num-acc}(c) = \text{num-acc}(d)$, $w$ is positive and $y \in \text{ideal}(c)$.
\end{proposition}

Proposition 17 allows us to show the decidability of repeated coverability under the following effectiveness hypothesis. A class $\mathcal{C}$ of WSTS is positive-effective if there is an algorithm that decides, on input $S = (X, \Sigma, \to, \leq) \in \mathcal{C}$ and a finite automaton $A$, whether the language of $A$ contains a positive sequence. VAS, Petri nets and $\omega$-Petri nets are positive-effective, since, for these models, testing whether a finite automaton $A$ accepts some positive sequence amounts to computing the Parikh image of $L(A)$, which is effectively semilinear [35].

\begin{theorem}
Repeated coverability is decidable for completion-post-effective, $\infty$-completion-effective and positive-effective classes of positive very-WSTS.
\end{theorem}

\begin{proof}
By Prop. 17, $y$ is repeatedly coverable from $x$ if and only if there are states $c, d$ in $A_{\lx}$ and $w \in \Sigma^+$ such that:

$$c \xrightarrow{w \cdot A} d, \text{num-acc}(c) = \text{num-acc}(d), w \text{ is positive and } y \in \text{ideal}(c).$$

(1)

We show how (1) can be tested. For every $c \in A_{\lx}$, let $A_c$ be the finite automaton over alphabet $\Sigma$ whose set of states is $Q_c \overset{\text{def}}{=} \{d \in A_{\lx} : c \xrightarrow{w \cdot A} d \text{ and } \text{num-acc}(c) = \text{num-acc}(d)\}$, the initial state is $c$, all states are accepting, and transitions are as in $A_{\lx}$. For every $d \in Q_c$ and $w \in \Sigma^*$, $c \xrightarrow{w \cdot A} d$ if and only if $w$ is in the language $L_c$ of $A_c$. Build a new finite automaton $A_c^+$ that recognizes $L_c \setminus \{\epsilon\}$. Let $C_y \overset{\text{def}}{=} \{c \in A_{\lx} : y \in \text{ideal}(c)\}$. By (1), $y$ is repeatedly coverable from $x$ if and only if there exists $c \in C_y$ such that the language $L_c \setminus \{\epsilon\}$ of $A_c^+$ contains a positive sequence. The latter is decidable since $\mathcal{C}$ is positive-effective, since $A_c^+$ can be constructed effectively for every $c$ (because $A_{\lx}$ can, using the fact that $\mathcal{C}$ is completion-post-effective and $\infty$-completion-effective), and since we can build $C_y$ by enumerating the states $c$ of $A_{\lx}$, checking whether $y \in \text{ideal}(c)$ for each (item (2) in the definition of completion-post-effectiveness).
\end{proof}
6.2 From model checking to repeated coverability

We conclude this section by reducing LTL model checking to repeated coverability. Recall that a Büchi automaton $B$ is a non-deterministic finite automaton $B = (Q, \Sigma, \delta, q_0, F)$ interpreted over $\Sigma^\omega$. An infinite word is accepted by $B$ if it contains an infinite path from $q_0$ labeled by $w$ and visiting $F$ infinitely often. We denote by $L(B)$ the set of infinite words accepted by $B$.

Let $B = (Q, \Sigma, \delta, q_0, F)$ be a Büchi automaton and let $S = (X, \Sigma, \leq)$ be a WSTS. The product of $B$ and $S$ is defined as $B \times S \overset{\text{def}}{=} (Q \times X, \Sigma \times Q, \leq)$ where $(p, x) \xrightarrow{(a,r)} (q, y)$ if $(p, a, r) \in \delta, q = r$ and $x \overset{a}{\rightarrow} y$. The point in including $r$ in the label is so that $\hat{B} \times S$ is deterministic, a requirement for very-WSTS. For every WSTS $S = (X, \Sigma, \leq)$, we extend $S$ with a new “minimal” element $\bot$ smaller than every other states, i.e. $S_\bot \overset{\text{def}}{=} (X \cup \{\bot\}, \Sigma, \leq)$ where transition relations are unchanged, and $\leq_\bot \overset{\text{def}}{=} \leq \cup \{(\bot, y) : y \in X \cup \{\bot\}\}$. It can be shown that if $S$ is a positive very-WSTS, then $B \times S_\bot$ is also. Taking the product of $B$ and $S_\bot$ allows us to test whether a word of $L(B)$ is also an infinite trace of $S$:

$\blacktriangleright$ Proposition 19. Let $B = (Q, \Sigma, \delta, q_0, F)$ be a Büchi automaton, let $S = (X, \Sigma, \leq)$ be a very-WSTS, and let $x_0 \in X$. There exists $w \in L(B) \cap \omega$-Traces$_S(x_0)$ if and only if there exists $q_f \in F$ such that $(q_f, \bot)$ is repeatedly coverable from $(q_0, x_0)$ in $B \times S_\bot$.

Theorem 18 and Proposition 19 imply the decidability of LTL model checking:

$\blacktriangleright$ Theorem 20. LTL model checking is decidable for completion-post-effective, $\infty$-completion-effective and positive-effective classes of positive very-WSTS.

Theorem 20 implies that LTL model checking for $\omega$-Petri nets is decidable. This includes, and generalizes strictly, the decidability of termination in $\omega$-Petri nets [25].

7 Discussion and further work

We have presented the framework of very-WSTS, for which we have given a Karp-Miller algorithm. This allowed us to show that ideal decompositions of coverability sets of very-WSTS are computable, and that LTL model checking is decidable under some additional assumptions. We have also characterized acceleration levels in terms of ordinal ranks. Finally, we have shown that downward traces inclusion is decidable for very-WSTS.

As future work, we propose to study well-structured models beyond very-WSTS for which there exist Karp-Miller algorithms, e.g. unordered data Petri nets (UDPN) [30, 29], or for which reachability is decidable, e.g. recursive Petri nets [28] with strict monotonicity. It is conceivable that LTL model checking is decidable for such models. Our approach will have to be extended to tackle this problem. For example, UDPN do not have finitely many acceleration levels. To circumvent this issue, Hofman et al. [29] make use of two types of accelerations that can be nested. One type is prioritized to ensure that acceleration levels along a branch grow “fast enough” for the algorithm to terminate.

References

4 Recursive Petri nets are WSTS for the tree embedding.

A Missing proofs of Section 3.1

Proposition 3 ([7]). The following holds for every WSTS \( S = (X, \Sigma^*, \leq) \):  
1. For all \( x, y \in X \) and \( w \in \Sigma^* \), if \( x \xrightarrow{w} y \), then for every ideal \( I \supseteq \downarrow x \), there exists an ideal \( J \supseteq \downarrow y \) such that \( I \nrightarrow J \).  
2. For all \( I, J \in \Idl(X) \) and \( w \in \Sigma^* \), if \( I \nrightarrow J \), then for every \( y \in J \), there exist \( x \in I \) and \( y' \in X \) such that \( x \xrightarrow{w^'} y' \) and \( y' \geq y \). If \( S \) has strong monotonicity, then \( w' = w \).

Proof.  
1. By induction on \(|w|\). When \(|w| = 0\), the claim is obvious. Otherwise, write \( w = av \), where \( a \in \Sigma, v \in \Sigma^*, |v| < |w| \), and let \( x \xrightarrow{a} z \xrightarrow{v} y \), for some state \( z \). Certainly \( z \) is in \( \Post_S(I,a) \), hence in \( \downarrow (\Post_S(I,a)) \). Write the ideal decomposition of the latter as \( \{I_1,I_2,\ldots,I_n\} \). For some \( k, 1 \leq k \leq n \), \( z \in I_k \), and by definition \( I \nrightarrow I_k \). By induction hypothesis, \( I_k \nrightarrow J \) for some ideal containing \( y \), whence the result.

2. By induction of \(|w|\) again. The case \(|w| = 0\) is obvious, too. Otherwise, write \( w = av \), where \( a \in \Sigma, v \in \Sigma^*, |v| < |w| \). There is an ideal \( K \) such that \( I \nrightarrow K \nrightarrow J \), and the induction hypothesis gives us elements \( z \in K \) and \( y' \in J \), and a word \( v' \in \Sigma^* \) such that \( z \xrightarrow{v'} y' \) and \( y' \geq y \). (Moreover, if \( S \) has strong monotonicity, then \( v' = v \).) By definition of \( \nrightarrow \), \( K \) is included in \( \downarrow \Post_S(I,a) \), so there are elements \( x \in I \) and \( z' \in K \) with \( z' \geq z \) such that \( x \xrightarrow{a} z' \). Since \( S \) is monotonic, there is a further element \( y'' \geq y' \) and a further word \( v'' \) such that \( z' \xrightarrow{v''} y'' \). (If \( S \) is strongly monotonic, \( v'' = v' \), so \( v'' = v \).) This entails that \( x \xrightarrow{av''} y'' \geq y \), and if \( S \) is strongly monotonic, \( av'' = av = w \).

3. Let \( J \in \Post_S(I,w) \) and let \( y \in J \). By (2), there exist \( x \in I \) and \( y' \in X \) such that \( x \xrightarrow{w} y' \) and \( y' \geq y \). Thus, \( y \in \downarrow \Post_S(x,w) \subseteq \downarrow \Post_S(I,w) \). Conversely, let \( y \in \downarrow \Post_S(I,w) \). There exist \( x \in I \) and \( y' \in X \) such that \( x \xrightarrow{w} y' \) and \( y' \geq y \). By (1), there exists an ideal \( J \supseteq \downarrow y' \supseteq \downarrow y \) such that \( I \nrightarrow J \). Thus, \( J \in \Post_S(I,w) \) and \( y \in J \).

4. For every \( w \in \Traces_S(x) \), there is a state \( y \) such that \( x \xrightarrow{w} y \). Use (1) on \( I = \downarrow x \): we obtain an ideal \( J \) such that \( I \nrightarrow J \), showing that \( w \in \Traces_S(\downarrow x) \). Conversely, for every \( w \in \Traces_S(\downarrow x) \), there is an ideal \( J \) such that \( I \nrightarrow J \), where \( I = \downarrow x \). Ideals are non-empty, so pick \( y \in J \). By (2), there are states \( x' \in I \) and \( y' \geq y \) such that \( x' \xrightarrow{w} y' \). The fact that \( x' \) is in \( I \), namely that \( x' \leq x \), allows us to invoke strong monotonicity and obtain a state \( y'' \geq y' \) such that \( x \xrightarrow{w} y'' \). In particular, \( w \) is in \( \Traces_S(x) \).

Let \( \omega \)-Traces_S(x). Let \( x_0 \overset{\text{def}}{=} x \), and let \( x_1, x_2, \ldots \in X \) be such that \( x \xrightarrow{w_1} x_1 \xrightarrow{w_2} x_2 \xrightarrow{w_3} \cdots \). Let \( I_0 \overset{\text{def}}{=} \downarrow x \). By (1), there exists an ideal \( I_1 \supseteq \downarrow x_1 \) such that \( I_0 \nrightarrow I_1 \). This process can be repeated using (1) to obtain \( I_{i-1} \nrightarrow I_i \) with \( I_i \supseteq \downarrow x_i \) for every \( i > 0 \). \( \square \)
B  Missing proofs of Section 3.3

The following proposition shows formally that accelerations are well-defined:

**Proposition 21.** Let \( S = (X, \xrightarrow{\cdot}, \leq) \) be a WSTS such that \( \hat{S} \) is deterministic and has strong-strict monotonicity. Let \( I \in \text{Idl}(X) \) and \( w \in \Sigma^+ \) be such that \( I \subset w(I) \). For every \( k \in \mathbb{N} \), \( w^k(I) \subset w^{k+1}(I) \).

**Proof.** Let \( m = |w| \). We proceed by induction on \( k \). The base case follows immediately. Let \( k > 0 \) and assume that the claim holds for \( k - 1 \). In particular, this implies that \( J = w^{k-1}(I) \) and \( K = w^k(I) \) are defined, and that \( J \subset K \).

There exist \( J_1, J_2, \ldots, J_m \in \text{Idl}(X) \) such that \( J \xrightarrow{w_1} J_1 \xrightarrow{w_2} \cdots \xrightarrow{w_m} J_m \). By strong-strict monotonicity of \( \hat{S} \), there exist \( K_1, K_2, \ldots, K_m \in \text{Idl}(X) \) such that \( K \xrightarrow{\hat{S}} K_1 \xrightarrow{\hat{S}} \cdots \xrightarrow{\hat{S}} K_m \) and \( J_i \subset K_i \) for every \( i \in [m] \). Therefore,

\[
\begin{align*}
w^k(I) &= w(J) \quad \text{(by definition of } J) \\
&= J_m \quad \text{(since } \hat{S} \text{ is deterministic)}
\end{align*}
\]

\[
\begin{align*}
&\subset K_m \\
&= w(K) \quad \text{(since } \hat{S} \text{ is deterministic)} \\
&= w^{k+1}(I) \quad \text{(by definition of } K) .
\end{align*}
\]

**Proposition 6.** Let \( S = (X, \xrightarrow{\cdot}, \leq) \) be a WSTS such that \( S \) has strong monotonicity, and \( \hat{S} \) is deterministic and has strong-strict monotonicity. For every \( I \in \text{Idl}(X) \) and \( w \in \Sigma^+ \),

1. if \( \text{Post}_S(I, w) \neq \emptyset \) and \( I \in \text{Acc}_n(X) \) for some \( n \in \mathbb{N} \), then \( w(I) \in \text{Acc}_n(X) \);
2. if \( I \subset w(I) \) and \( I \in \text{Acc}_n(X) \) for some \( n \in \mathbb{N} \), then \( w^\infty(I) \in \text{Acc}_{n+1}(X) \).

**Proof.**

1. Suppose that \( w(I) \) is defined, i.e., that \( \text{Post}_S(I, w) \neq \emptyset \). We proceed by induction on \( n \).

   If \( n = 0 \), then we are done since \( w(I) \in \text{Idl}(X) = \text{Acc}_0(X) \).

   Assume \( n > 0 \) and that the claim holds for \( n - 1 \). There exist \( I_1, I_2, \ldots \in \text{Acc}_{n-1}(X) \) such that \( I_1 \subset I_2 \subset \cdots \) and \( I = \bigcup_{i \in \mathbb{N}} I_i \). Let \( A = \{ i \in \mathbb{N} : \text{Post}_S(I_i, w) \neq \emptyset \} \). We have

\[
w(I) = \downarrow \text{Post}_S(I, w) = \bigcup_{i \in A} \text{Post}_S(I_i, w) = \bigcup_{i \in A} w(I_i),
\]

where the first equality follows from Prop. 3(3). Therefore, \( A \) cannot be empty. Let \( i \in A \) and \( j > i \). Since \( I_i \subset I_j \), we have \( w(I_i) \subset w(I_j) \) by strong-strict monotonicity of \( \hat{S} \). This implies that \( j \in A \) and, in particular, that \( A \) is infinite. We conclude that \( w(I) \in \text{Acc}_n(X) \) since, by induction hypothesis, \( w(I_i) \in \text{Acc}_{n-1}(X) \) for every \( i \in A \).

2. Since \( I \subset w(I) \), we have \( w^\infty(I) = \bigcup_{k \in \mathbb{N}} w^k(I) \) and the sequence \( I \subset w(I) \subset w^2(I) \subset \cdots \subset w^k(I) \subset \cdots \) is strictly increasing by Proposition 21. By (1), \( w^k(I) \in \text{Acc}_n(X) \) for every \( k \in \mathbb{N} \). Therefore, \( w^\infty(I) \in \text{Acc}_{n+1}(X) \). ▶

19        Work ← Work ∪ {d}
20  return Nodes

D  Missing proofs of Section 4.1

We prove Prop. 11(1):

► Proposition 11. Let S = (X, Σ, ≤) be a very-WSTS and let I₀ ∈ Idl(X).
1. For every y, z ∈ X, w ∈ Σ* and c ∈ A_{I₀}, if y \xrightarrow{w} z and y ∈ ideal(c), then there exists d ∈ A_{I₀} such that c \xrightarrow{w} A d and z ∈ ideal(d).
2. For every z ∈ X, w ∈ Σ* and c, d ∈ K_{I₀}, if c \xrightarrow{w} K d and z ∈ ideal(d), then there exist y ∈ ideal(c), w′ ≥ w and z′ ≥ z such that y \xrightarrow{w′} z′.

Proof. We prove (1) by induction on |w|. If |w| = 0, then w = ε, which implies z = y. Thus, it suffices to take d ≡ a.

Assume |w| > 0 and that the claims holds for words of length less than |w|. There exist u ∈ Σ*, a ∈ Σ and y′ ∈ X such that w = ua and y \xrightarrow{u} y′ \xrightarrow{a} z. By induction hypothesis, there exists a node c′ ∈ A_{I₀} such that c \xrightarrow{u} A c′ and y′ ∈ ideal(c′). Let I ≡ ideal(c′). Since y′ \xrightarrow{a} z and y′ ∈ I, there exists some J ∈ Idl(X) such that z ∈ J and I \xrightarrow{a} J. If c′ has a successor under a labeled by J, then we are done. Otherwise, there are two cases to consider.

= If c′ has no successor under a, then c′ must be a leaf of T_{I₀}. Thus, c′ has an ancestor c'' in T_{I₀} such that ideal(c′) = ideal(c''). Thus, c' \xrightarrow{u} A c''. Now, c'' has a successor d under...
Let $\alpha$, otherwise it would also be a leaf of $T_{\alpha}$, which is impossible. Therefore, $J = \ideal(d)$, and hence $c \rightarrow_{\mathcal{A}} c' \rightarrow_{\mathcal{A}} c'' \rightarrow_{\mathcal{A}} d$ and $z \in \ideal(d)$.

- If $c$ has a successor $d$ under $a$, then $J$ has been accelerated. Therefore, $\ideal(d) = v^\omega(J)$ for some $v \in \Sigma^+$. By definition of accelerations, $J \subseteq v^\omega(J)$. Therefore, $c \rightarrow_{\mathcal{A}} c' \rightarrow_{\mathcal{A}} c'' \rightarrow_{\mathcal{A}} d$ and $y \in \ideal(d)$.

\begin{proof}
1. $\subseteq$: Let $y \in D_I$. There exist $w \in \Sigma^*$ and $c \in K_I$ such that $r_\mathcal{K} c$ and $y \in \ideal(c)$.

By Prop. 11(2), there exist $x \in I$, $w' \geq w$ and $y' \geq y$ such that $x \xrightarrow{w'} y$. Hence, $y \in \post{\mathcal{S}}{I}(x) \subseteq \post{\mathcal{S}}{I}(J_0) \subseteq \down T_I$.

$\supseteq$: Let $y \in \down T_I$. There exist $x \in I$, $w \in \Sigma^*$ and $y' \geq y$ such that $x \xrightarrow{w} y'$. By Prop. 11(1), there exists a node $c \in A_I$ such that $r_\mathcal{A} c$ and $y' \in \ideal(c)$. Since ideals are downward closed, $y \in \ideal(c)$ which implies that $y \in D_I$.

2. Let $w \in \Traces{\mathcal{S}}{I}$. There exist $x \in I$ and $y \in X$ such that $x \xrightarrow{w} y$. By Prop. 11(1), there exists a node $c \in A_I$ such that $r_\mathcal{A} c$ and $y \in \ideal(c)$. Therefore, $w \in L(A_I)$.

3. Let $w \in L(K_I)$. There exists a node $c \in K_I$ such that $r_\mathcal{K} c$. Let $y \in \ideal(c)$. By Prop. 11(2), there exist $x \in I$, $w' \geq w$ and $y' \geq y$ such that $x \xrightarrow{w'} y'$. Therefore, $w \in \down T_I$ since $w \leq w'$.

\end{proof}

\begin{corollary}
For every very-WSTS $\mathcal{S} = (X, \xrightarrow{\Sigma}, \leq)$ and every state $x \in X$,

$D_{\down x} = \down \post{\mathcal{S}}{x}$ and $\down L(K_{\down x}) = \down \Traces{\mathcal{S}}{x}$.

In particular, $\down \Traces{\mathcal{S}}{x}$ is a regular language computable from $\mathcal{S}$ and $x$.

\end{corollary}

\begin{proof}
- By Theorem 10, we have $D_{\down x} = \down \post{\mathcal{S}}{x}$. Moreover, by strong monotonicity of $\mathcal{S}$, we have $\down \post{\mathcal{S}}{x} = \down \post{\mathcal{S}}{x}$.

- By Theorem 10, we have $\Traces{\mathcal{S}}{\down x} \subseteq L(A_{\down x}) \subseteq L(K_{\down x}) \subseteq \down \Traces{\mathcal{S}}{x}$.

Therefore $\down \Traces{\mathcal{S}}{x} = \down L(A_{\down x}) = \down L(K_{\down x})$. Moreover, by strong monotonicity of $\mathcal{S}$, we have $\Traces{\mathcal{S}}{\down x} = \Traces{\mathcal{S}}{x}$.

\end{proof}

E Missing proofs of Section 5

We first prove the following claim made in Section 5:

\begin{proposition}
$A_\alpha(\mathbb{N}^d_\omega)$ is the set of $d$-tuples with less than $\alpha$ components equal to $\omega$.

\end{proposition}
Proof. Using the fact that $A_\alpha(N^d_\omega)$ grows as $\alpha$ grows, it suffices to show the claim for $\alpha \leq d + 1$. This is shown by induction on $\alpha$. The case $\alpha = 0$ is obvious.

Let $1 \leq \alpha \leq d + 1$. If $x = (x_1, \ldots, x_d) \in N_\omega$ has at least $\alpha$ components equal to $\omega$, we obtain an acceleration candidate by picking an index $j$ such that $x_j = \omega$, and forming the tuples $(x_1, \ldots, x_{j-1}, i, x_{j+1}, \ldots, x_d)$ for $i \in \mathbb{N}$. By induction hypothesis, these tuples have at least $\alpha - 1$ components equal to $\omega$ and therefore cannot be in $A_{\alpha-1}(N^d_\omega)$. This entails that $x$ cannot be in $A_\alpha(N^d_\omega)$.

Conversely, assume that $x = (x_1, \ldots, x_d)$ has less than $\alpha$ components equal to $\omega$, say at positions $1, 2, \ldots, n < \alpha$. (The general case is obtained by applying a permutation of the indices.) There are only finitely many letters $y \leq x$ that have their first $n$ components equal to $\omega$. Therefore any acceleration candidate below $x$, being infinite, must contain a tuple with at most $n - 1$ components equal to $\omega$. Since $n < \alpha - 1$, by induction hypothesis it must go through $A_{\alpha-1}(N^d_\omega)$, showing that $x \in A_\alpha(N^d_\omega)$.

We prove the following claim made in Section 5:

**Proposition 24.** $\text{rk Idl}(\Sigma^*) = \omega^{[d]} + 1$ for every finite alphabet.

Proof. Let $k \equiv [d]$. The elements of $\text{Idl}(\Sigma^*)$ are word-products $P$, defined as formal products $e_1 e_2 \cdots e_m$ of atomic expressions of the form $a^\alpha$, $a \in \Sigma$, or $A^*$, where $a^\beta$ denotes $\{a, \varepsilon\}$ and $A$ is a non-empty subset of $\Sigma$ [31, 19]. Word-products were introduced under this name in [3].

**Lower bound.** Enumerate the letters of $\Sigma$ as $a_1, a_2, \ldots, a_k$. Let $A_i = \{a_1, a_2, \ldots, a_i\}$. Any ordinal $\alpha$ strictly less than $\omega^k$ can be written in a unique way as $\omega^{k-1} \cdot n_{k-1} + \omega^{k-2} \cdot n_{k-2} + \cdots + \omega \cdot m_1 + m_0$. Define an ideal $I_\alpha$ by the word-product

$$(a_1^\alpha a_2^{\alpha_1} a_3^{\alpha_2} \cdots a_k^{\alpha_{k-1}})^{n_k} a_k^{n_{k-1}} \cdot \cdots \cdot a_2^{n_1} a_1^{n_0}.$$

The first terms, $n_0$ times $a_1^\alpha$, have a different format from the rest of the word-product. For uniformity of treatment, we write $a_1^\alpha$ as $a_1^{\alpha_1} A_0^\alpha$ (indeed $A_0^{\alpha} = \emptyset = \{\varepsilon\}$), so $I_\alpha = (a_1^{\alpha_1} A_0^{\alpha})^{n_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{n_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{n_{k-1}}$.

We claim that $\beta > \alpha$ implies $I_\beta \supset I_\alpha$.

Let $\alpha = \omega^{k-1} \cdot n_{k-1} + \omega^{k-2} \cdot n_{k-2} + \cdots + \omega \cdot m_1 + m_0$ and $\beta = \omega^{k-1} \cdot m_{k-1} + \omega^{k-2} \cdot m_{k-2} + \cdots + \omega \cdot m_1 + m_0$. The condition $\beta > \alpha$ is equivalent to the fact that $(m_{k-1}, m_{k-2}, \ldots, m_1, m_0)$ is lexicographically larger than $(n_{k-1}, n_{k-2}, \ldots, n_1, n_0)$. Write $\beta = \alpha$ if for some $i$ with $0 \leq i < k$, $n_{k-1} = m_{k-1}$, $n_{k-2} = m_{k-2}$, $\ldots$, $n_{i+1} = m_{i+1}$, and $n_i = n_i + 1$. Since $\alpha > \beta$ is the transitive closure of $\to$, it suffices to show that $\beta = \alpha$ implies $I_\beta \supset I_\alpha$.

Containment is proved as follows. $I_\beta = (a_1^{\alpha_1} A_0^{\alpha})^{n_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{n_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{n_{k-1}}$ contains $(a_1^{\alpha_1} A_0^{\alpha})^{m_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}}$, because the empty word belongs to the removed prefix $(a_1^{\alpha_1} A_0^{\alpha})^{m_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}}$. Since $m_i = n_i + 1 \geq 1$, we can write $(a_1^{\alpha_1} A_0^{\alpha})^{m_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}}$ as $a_1^{\alpha_1} A_0^{\alpha} P_1$, where $P_1$ abbreviates $(a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} (a_3^{\alpha_2} A_2^{\alpha_1})^{m_2} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}}$. Hence $I_\beta$ contains $A_0^{\alpha} P_1$. By the definition of $\to$, $P_1$ is equal to $(a_1^{\alpha_1} A_0^{\alpha})^{m_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}}$. We now note that $A_0^{\alpha} P_1$ contains $(a_1^{\alpha_1} A_0^{\alpha})^{m_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}}$, because every word in the latter contains only letters from $\{a_1, a_2, \ldots, a_k\} = A_0$. Hence $A_0^{\alpha} P_1$ contains $(a_1^{\alpha_1} A_0^{\alpha})^{m_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}} P_0$, which is equal to $I_\alpha$ since $I_\beta$ contains $A_\alpha^{\alpha} P_0$. We conclude.

We now show that containment is strict. Let $w$ be the word $w_1^{m_0} (a_2 a_1)^{m_1} (a_3 a_2)^{m_2} \cdots (a_k a_{k-1})^{m_{k-1}}$. Clearly, $w$ is in $I_\beta$. To show that $w$ is not in $I_\alpha$, we show that $u(a_1 + a_1)^{n_1 + 1}$ $(a_1 + a_1 a_1)^{m_1} \cdots (a_1 + a_1)^{m_{k-1}}$ is not in $L(a_1^{\alpha_1} A_0^{\alpha})^{m_0} (a_2^{\alpha_2} A_1^{\alpha_1})^{m_1} \cdots (a_k^{\alpha_{k-1}} A_{k-1}^{\alpha_{k-2}})^{m_{k-1}}$ for any $j$, $i + 1 \leq j \leq k$, where $u$ is an arbitrary word in $A_0^{\alpha}$ and $L$ is an arbitrary language included in $A_0^{\alpha}$. We will obtain $u \not\in I_\alpha$ by letting $j = k$, $u = a_1^{m_0} (a_2 a_1)^{m_1} \cdots (a_i a_{i-1})^{m_{i-1}}$.
and \( L = (a_1^2 A_0^2)^{n_0} (a_2^2 A_0^2)^{n_1} (a_3^2 A_{i-1}^2)^{n_2} \cdots (a_j^2 A_{i-1}^2)^{n_{i-1}} \). This is by induction on \( j - (i + 1) \).

If \( j = i + 1 \), we must show that \( v(a_{i+1})^{n_{i+1}} \) is not in \( L(a_{i+1} A_i) \), and that is obvious since any word in \( L(a_{i+1} A_i) \) can contain at most \( n_i \) occurrences of \( a_{i+1} \). In the induction case, let \( v = u(v_{i+1} A_i)^{n_{i+1}} (a_i + 2 a_{i+1}) \cdots (a_j a_{i-1})^{m_{j-1}} A_l (a_{i+2} A_{i+1})^{m_{i+1}} \cdots (a_j A_{i-1})^{m_{j-1}} \), and let us show that \( v(a_j A_j)^{m_j} \) is not in \( L(a_j A_j) \), knowing that \( v \notin A \) by induction hypothesis. If \( v(a_j A_j)^{m_j} \) were in \( L(a_j A_j) \), there would be two words \( v_1 \in A \) and \( v_2 \in (a_j^2 A_j)^{m_j} \) such that \( v(a_j A_j)^{m_j} = v_1 v_2 \). Since \( v_2 \) is a suffix of \( v(a_j A_j)^{m_j} \) and is in \( (a_j A_j)^{m_j} \), \( v_2 \) must in fact be a suffix of \( (a_j A_j)^{m_j} \). Hence \( v_1 \) contains \( v \) as prefix. However, \( v_1 \) is in \( A \) and \( A \) is downward-closed, and that implies \( v \in A \) in particular: contradiction.

This ends our proof that \( \beta > \alpha \) implies \( I_\beta \supset I_\alpha \). Since \( I_\beta \supset I_\alpha \) implies \( rk I_\beta > rk I_\alpha \), an easy ordinal induction shows that \( rk I_\alpha \geq \alpha \) for every ordinal \( \alpha < \omega^b \). There is a further ideal \( A_i^* = \Sigma^* \) in \( \Sigma^* \). It contains every \( I_\alpha \), and strictly so since the number of occurrences of \( a_k \) in any word of \( I_\alpha \) is bounded from above by \( n_k - 1 \) (where \( \alpha = k^{b-1} \cdot k_{i-1} + k^{i-2} \cdot n_k - 2 + \cdots + \omega \cdot n_1 + n_0 \)), but there are words with arbitrarily many occurrences of \( a_k \) in \( A_i^* \).

It follows that the rank of \( A_i^* \) in \( \text{Idl}(\Sigma^*) \) is at least \( sup \{ \alpha + 1 \mid \alpha < \omega^b \} = \omega^b \), and therefore that the rank of \( \text{Idl}(\Sigma^*) \) is at least \( \omega^b + 1 \).

**Upper bound.** Order atomic expressions by: \( A^* \sqsubseteq B^* \) if and only if \( A \subseteq B \), \( a^* \sqsubseteq B^* \) if and only if \( a \in B \), and no other strict inequality holds. The relation \( \sqsubseteq \) is simply strict inclusion of the corresponding ideals. A word-product \( P = e_1 e_2 \cdots e_m \) is reduced if and only if the ideal \( e_i e_{i+1} \) is included neither in \( e_i \) nor in \( e_{i+1} \), for every \( i, 1 \leq i < m \). Reduced word-products are normal forms for word-products \([3]\). On reduced word-products, we define two binary relations \( \sqsubset \) and \( \sqsubseteq \) by the following rules, and the specification that \( \sqsubset \) is the reflexive closure of \( \sqsubseteq \):

\[
\begin{align*}
& eP \sqsubseteq P' \quad P \sqsubset P' \quad \forall i \cdot e_i \sqsupset A^* \quad P \sqsubset P' \quad P \sqsubseteq P' \\
& eP \sqsubset e'P' \quad a^*P \sqsubset a^*P' \quad e_1 \cdots e_k P \sqsubset e_i A^*P' \quad A^*P \sqsubset e_i A^*P' \quad A^*P \sqsubset A^*P'
\end{align*}
\]

Those rules are taken from \([27, \text{Figure 1}]\), and specialized to the case where all letters from \( \Sigma \) are incomparable. (That means that the rule called \((w2)\) there never applies, and we have kept the remaining rules \((w1), (w3)-\text{}(w5)\).) For reduced word-products \( P \) and \( P' \), \( P \sqsubset P' \) if and only if \( P \), as an ideal, is strictly contained in \( P' \) (loc.cit.; alternatively, this is an easy exercise from the characterization of [non-strict] inclusion in \([3]\).) It follows that if \( P \) is strictly below \( P' \) in \( \text{Idl}(\Sigma^*) \), then \( \mu(P) \) is strictly below \( \mu(Q) \) in the multiset extension of \( \sqsubset \), where, for \( P = e_1 e_2 \cdots e_m \), \( \mu(P) \) is the multiset \( \{e_1, e_2, \ldots, e_m\} \), a fact already used in \([27]\).

The set of atomic expressions consists of the following elements: elements of the form \( a^* \) are at the bottom, and have rank 1; just above, we find \( \{a\}^* \), of rank 2, then \( \{a, b\}^* \) of rank 3, etc.. In other words, \( A^* \) has rank one plus the cardinality of \( A \). In particular, all atomic expressions except \( \Sigma^* \) have rank at most \( k \).

Among reduced word-products \( P \), those that are different from \( \Sigma^* \) must be of the form \( e_1 e_2 \cdots e_m \) where no \( e_i \) is equal to \( \Sigma^* \). This is by definition of reduction. Hence the suborder of those reduced word-products \( P \neq \Sigma^* \) has rank less than or equal to the set of multisets \( \{e_1, e_2, \ldots, e_m\} \) where each \( e_i \) has rank at most \( k \) (in the set of atomic expressions different from \( \Sigma^* \)).

The rank of the set of multisets of elements, where each element has rank at most \( k \), is at most \( \omega^k \). This is well-known, but here is a short argument. We can map any multiset \( \{e_1, e_2, \ldots, e_m\} \) to the ordinal \( \omega^{k-1} \cdot n_k - 1 + \omega^{k-2} \cdot n_{k-2} + \cdots + \omega \cdot n_1 + n_0 \) where \( n_i \) counts the number of elements \( e_i \) of rank \( i \), and we observe that this mapping is strictly monotone.

It follows that the suborder of those reduced word-products \( P \) that are different from \( \Sigma^* \)
Forward Analysis for WSTS, Part III: Karp-Miller Trees

has rank at most $\omega^k$. $\text{Idl}(\Sigma^*)$ contains just one additional element, $\Sigma^*$, which is therefore of rank at most $\omega^k$. Hence $\text{Idl}(\Sigma^*)$ has rank at most $\omega^k + 1$.

**F Missing proofs of Section 6.1**

To prove Prop. 17, we first prove two useful observations on the stuttering automaton:

**Proposition 25.** Let $S = (X, \Sigma, \leq)$ be a very WSTS and let $I_0 \in \text{Idl}(X)$. Let $c, d \in T_{I_0}$. The following holds:

1. If $c \overset{w}{\rightarrow} d$ and $\text{ideal}(c) = \text{ideal}(d)$, then $\text{num-acc}(c) = \text{num-acc}(d)$.
2. If $c \overset{w}{\rightarrow} d$, then $\text{num-acc}(c) \leq \text{num-acc}(d)$.

**Proof.**

1. For the sake of contradiction, suppose that $\text{num-acc}(c) \neq \text{num-acc}(d)$. This means that at least one acceleration occurred between $c$ and $d$. Let $c'$ be the first accelerated node, i.e. the first node such that $\text{num-acc}(c') = \text{num-acc}(c) + 1$ and $c \overset{c'}{\rightarrow} d$. Let $n$ be the largest $n \in \mathbb{N}$ such that $\text{ideal}(c) \in \text{Acc}_n(X)$. By Prop. 6(2), $c' \overset{\omega}{\rightarrow} c \overset{\omega}{\rightarrow} d$.

Moreover, by Prop. 6, $\text{ideal}(d) \in \text{Acc}_{n+k}(X)$ for some $k \geq 1$. This is a contradiction since $\text{ideal}(d) = \text{ideal}(c)$.

2. Since $c$ can reach $d$, there exist a path of length $n \geq 0$ from $c$ to $d$ in $A_{I_0}$. Let $c_0, c_1, \ldots, c_n$ be the nodes visited by this path, where $c_0 = c$ and $c_n = d$. We prove the claim by induction on $n$. If $n = 0$, then $c = d$ and the claim trivially holds. Assume that $n > 0$ and the claims holds for $n-1$. By induction hypothesis, $\text{num-acc}(c_0) \leq \text{num-acc}(c_{n-1})$.

If $c_n$ is an ancestor of $c_{n-1}$ such that $\text{ideal}(c_{n-1}) = \text{ideal}(c_n)$, then we are done since $\text{num-acc}(c_{n-1}) = \text{num-acc}(c_n)$ by (1). Otherwise, $c_{n-1} \overset{\omega}{\rightarrow} c_a$ for some $a \in \Sigma$. By Prop. 6, $\text{num-acc}(c_n) = \text{num-acc}(c_{n-1})$ or $\text{num-acc}(c_n) = \text{num-acc}(c_{n-1}) + 1$.

We may now prove Prop. 17.

**Proposition 17.** Let $S = (X, \Sigma, \leq)$ be a positive very WSTS, and let $x, y \in X$. State $y$ is repeatedly coverable from $x$ if and only if there are states $c, d$ of the stuttering automaton $A_{I_x}$ and $w \in \Sigma^+$ such that $c \overset{w}{\rightarrow} d$, $\text{num-acc}(c) = \text{num-acc}(d)$, $w$ is positive and $y \in \text{ideal}(c)$.

**Proof.** $\Rightarrow$) Assume $y$ is repeatedly coverable from $x$. There exist $y_0, y_1, \ldots \in X$, $v_0 \in \Sigma^*$ and $v_1, v_2, \ldots \in \Sigma^+$ such that $x \overset{v_0}{\rightarrow} y_0 \overset{v_1}{\rightarrow} y_1 \overset{v_2}{\rightarrow} \cdots$ and $y_i \geq y$ for every $i \in \mathbb{N}$. By Prop. 11(1), there exist $c_0, c_1, \ldots \in A_{I_x}$ such that $r \overset{\omega}{\rightarrow} c_0 \overset{\omega}{\rightarrow} c_1 \overset{\omega}{\rightarrow} \cdots$ and $y_i \in \text{ideal}(c_i)$ for every $i \in \mathbb{N}$. By Prop. 25(2), $\text{num-acc}(c_i) \leq \text{num-acc}(c_{i+1})$ for every $i \in \mathbb{N}$. Since finitely many accelerations can occur along this path, there exists some $\ell \in \mathbb{N}$ such that $\text{num-acc}(c_i) = \text{num-acc}(c_j)$ for every $i, j \geq \ell$. Since $X$ is well-quasi-ordered, there exist $\ell \leq i < j$ such that $y_i \leq y_j$. Let $u \overset{\omega}{=} v_0 v_1 \cdots v_i$ and $w \overset{\omega}{=} v_{i+1} \cdots v_j$. We are done since $c_i \overset{w}{\rightarrow} c_j$, $|w| > 0$, $\text{num-acc}(c_i) = \text{num-acc}(c_j)$ and $w$ is positive for $y_i$ which implies that $w$ is positive by positivity of $S$.

$\Leftarrow$) Let $c, d \in A_{I_x}$, $w \in \Sigma^+$ and $y' \in X$ be such that $c \overset{w}{\rightarrow} d$, $\text{num-acc}(c) = \text{num-acc}(d)$, $w$ is positive, and $y \in \text{ideal}(c)$. Since no acceleration occurs from $c$ to $d$, we have $\text{ideal}(c) \overset{\omega}{=} \text{ideal}(d)$. Therefore, there exists $y' \in \text{ideal}(c)$ such that $\text{Post}_S(y', w) \neq \emptyset$. In particular, by positivity of $S$, this implies that $w$ is positive for $y'$. Since $\text{ideal}(c)$ is directed and $y \in \text{ideal}(c)$, there exists $z \in \text{ideal}(c)$ such that $z \geq y'$ and $z \geq y$. Let $u \overset{\omega}{=} v_0 v_1 \cdots v_i$ be the path from $r$ to $c$ in $T_{I_x}$. By Prop. 11(2), there exist $x' \in \text{ideal}(r)$, $u' \geq u$ and $z' \geq z$ such that $x' \overset{w'}{\rightarrow} z'$. Since $\text{ideal}(r) = \downarrow x$, we have $x' \leq x$. By strong monotonicity of $S$, $x \overset{w'}{\rightarrow} z'$.
for some $z'' \geq z'$. Since $z'' \geq y'$ and $S$ is positive, $w$ is positive for $z''$. Let $y_0 \overset{w}{\rightarrow} z''$. There exists $y_1 \geq y_0$ such that $y_0 \overset{w}{\rightarrow} y_1$. By successive application of strong monotonicity of $S$, we obtain $y_2, y_3, \ldots \in X$ such that $y_i \overset{w}{\rightarrow} y_{i+1}$ and $y_{i+1} \geq y_i$ for every $i \in \mathbb{N}$. Therefore, $x \overset{w'}{\rightarrow} y_0 \overset{w}{\rightarrow} y_1 \overset{w}{\rightarrow} \cdots$ and we are done since $y_i \geq y_0 = z'' \geq z' \geq z \geq y$ for every $i \in \mathbb{N}$. ◀

G Missing proofs of Section 6.2

We first prove the claims made on $S \times B$ and $S_\perp$ in Section 6.2.

Proposition 26. Let $B = (Q, \Sigma, \delta, q_0, F)$ be a Büchi automaton and let $S = (X, \Sigma, \rightarrow, \leq)$ be a very-WSTS. The product $B \times S$ is a very-WSTS. Moreover, if $S$ is positive, then $B \times S$ is also positive.

Proof. Let us show that $B \times S$ is a WSTS with strong monotonicity. Since equality is a wqo for finite sets and since wqos are closed under cartesian product, $\equiv \leq$ is a wqo. Let $(p, q) \in Q, \ x, x', y \in X$ and $(a, r) \in \Sigma \times Q$ be such that

$$(p, x) \overset{(a, r)}{\rightarrow} (q, y) \text{ and } x' \geq y.$$

By definition of $B \times S$, we have $(p, a, q) \in \delta$, $r = q$ and $x \overset{a}{\rightarrow} y$. By strong monotonicity of $S$, there exists $y' \geq y$ such that $x' \overset{a}{\rightarrow} y'$. Therefore, $(p, x') \overset{(a, r)}{\rightarrow} (q, y')$.

It remains to show that the completion of $B \times S$ is a deterministic WSTS with strong-strict monotonicity, and that $\text{Idl}(Q \times X)$ has finitely many levels. First note that

$$\text{Idl}(Q \times X) = \{\{q\} \times I : q \in Q, I \in \text{Idl}(X)\}. \tag{2}$$

Since $\text{Idl}(X)$ has finitely many levels, it follows from (2) that $\text{Idl}(Q \times X)$ also has finitely many levels. Similarly, $\text{Idl}(Q \times X)$ is well-quasi-ordered by $\subseteq$ since $\text{Idl}(X)$ is well-quasi-ordered by $\subset$ and since $Q$ is finite.

Strong-strict monotonicity. Let $I, I', J \in \text{Idl}(Q \times X)$, $a \in \Sigma$ and $r \in Q$ be such that $I \subseteq I'$ and $I^{(a, r)} \overset{I}{\rightarrow} J$. By (2), there exist $p, q \in Q$ and $I_p, I'_p, J_q \in \text{Idl}(X)$ such that $I = \{p\} \times I_p$, $I' = \{p\} \times I'_p$ and $J = \{q\} \times J_q$. We have $I_p \subseteq I'_p$, $I_p \overset{a}{\rightarrow} J_q$, $q = r$ and $(p, a, r) \in \delta$. By strong-strict monotonicity of $\hat{S}$, there exists $J'_q \in \text{Idl}(X)$ such that $I'_p \overset{a}{\rightarrow} J'_q$ and $J_q \subseteq J'_q$. Let $J' \overset{def}{=} \{q\} \times J'_q$. We obtain $I^{(a, r)} \overset{I}{\rightarrow} J'$ and $I \subseteq J'$.

Determinism. Let $I, J, J' \in \text{Idl}(Q \times X)$, $a \in \Sigma$ and $r \in Q$ be such that $I^{(a, r)} \overset{I}{\rightarrow} J$ and $I^{(a, r)} \overset{I}{\rightarrow} J'$. By (2), there exist $p, q, q' \in Q$ and $I_p, J_q, J'_q \in \text{Idl}(X)$ such that $I = \{p\} \times I_p$, $J = \{q\} \times J_q$ and $J' = \{q'\} \times J'_q$. We have $r = q = q'$, $I_p \overset{a}{\rightarrow} J_q$ and $I_p \overset{a}{\rightarrow} J'_q$. Since $\hat{S}$ is deterministic, we have $J_q = J'_q$. Therefore, $J = J'$.

Positivity. Suppose $S$ is positive. Let $u = (a_1, r_1)(a_2, r_2) \cdots (a_k, r_k) \in (\Sigma \times Q)^*$ be positive for $(p, x) \in Q \times X$ in $B \times S$. Let $(p', x') \in Q \times X$ be such that $\text{Post}_{B \times S}(p', x') \neq \emptyset$. We must show that $u$ is positive for $(p', x')$. Since $u$ is positive for $(p, x)$, there exists $(q, y) \geq (p, x)$ such that $(p, x) \overset{u}{\rightarrow} (q, y)$. We have $x \leq y$ and $x \overset{a_1 a_2 \cdots a_k}{\rightarrow} y$. Therefore, $(p, x) \overset{u}{\rightarrow} (q, y')$. By positivity of $S$, there exists $y' \geq x'$ such that $x' \overset{a_1 a_2 \cdots a_k}{\rightarrow} y'$. Therefore, $(p, x) \overset{u}{\rightarrow} (q, y')$ and $(p, x') \subseteq (q, y')$. ◀

Proposition 27. $S_\perp$ is a very-WSTS for every very-WSTS $S$. Moreover, if $S$ is positive, then $S_\perp$ is positive.
\textbf{Proof.} It is readily seen that $X \cup \{ \bot \}$ is a wqo and that $S_\bot$ preserves the strong monotonicity of $S$. Note that $\text{Idl}(X \cup \{ \bot \}) = \{ \bot \} \cup \{ I \cup \{ \bot \} : I \in \text{Idl}(X) \}$. Since inclusion is a wqo for $\text{Idl}(X)$, it is also a wqo for $\text{Idl}(X \cup \{ \bot \})$. Moreover, $\text{Idl}(X \cup \{ \bot \})$ has as many levels as $\text{Idl}(X)$.

Let $\rightsquigarrow_\bot$ denote the transition relation of the completion of $S_\bot$. For every $I, J \in \text{Idl}(X)$ and \( a \in \Sigma \), we have $I \overset{a}{\rightsquigarrow} J$ if and only if $I \cup \{ \bot \} \overset{a}{\rightsquigarrow} J \cup \{ \bot \}$. Therefore, the completion of $S_\bot$ is also deterministic and also has strong-strict monotonicity.

Note that $\text{Post}(x, w) \neq \emptyset$ implies that $x \neq \bot$. Therefore, since $S_\bot$ and $S$ share the same transition relations, $S_\bot$ preserves positivity of $S$.

We now prove Proposition 19.

\textbf{Proposition 19.} Let $B = (Q, \Sigma, \delta, q_0, F)$ be a Büchi automaton, let $S = (X, \rightarrow, \leq)$ be a very-WSTS, and let $x_0 \in X$. There exists $w \in L(B) \cap \omega\text{-Traces}(x_0)$ if and only if there exists $q_f \in F$ such that $(q_f, \bot)$ is repeatedly coverable from $(q_0, x_0)$ in $B \times S_\bot$.

\textbf{Proof.} $\Rightarrow$) Let $w \in L(B) \cap \omega\text{-Traces}(x_0)$. Since $w \in L(B)$, there exist $q_1, q_2, \ldots \in Q$ such that $q_0 \overset{w_1}{\rightarrow} q_1 \overset{w_2}{\rightarrow} q_2 \overset{w_3}{\rightarrow} \cdots$ and $q_i \in F$ for infinitely many $i \in \mathbb{N}$. Since $F$ is finite, there exists some $q_f \in F$ such that $q_i = q_f$ for infinitely many $i \in \mathbb{N}$. Since $w \in \omega\text{-Traces}(x_0)$, there exist $x_1, x_2, \ldots \in X$ such that $x_0 \overset{w_1}{\rightarrow} x_1 \overset{w_2}{\rightarrow} x_2 \overset{w_3}{\rightarrow} \cdots$. Therefore,

$$(q_0, x_0) \overset{(w_1, q_1)}{\rightarrow} (q_1, x_1) \overset{(w_2, q_2)}{\rightarrow} (q_2, x_2) \overset{(w_3, q_3)}{\rightarrow} \cdots$$

which implies that $(q_f, \bot)$ is repeatedly coverable from $(q_0, x_0)$ in $B \times S_\bot$ since $x_i \geq \bot$ for every $i \in \mathbb{N}$.

$\Leftarrow$) Suppose $(q_f, \bot)$ is repeatedly coverable from $(q_0, x_0)$ in $B \times S_\bot$. There exist $(a_1, q_1), (a_2, q_2), \ldots \in \Sigma \times Q$ and $(q_1, x_1), (q_2, x_2), \ldots \in Q \times X$ such that

$$(q_0, x_0) \overset{(a_1, q_1)}{\rightarrow} (q_1, x_1) \overset{(a_2, q_2)}{\rightarrow} (q_2, x_2) \overset{(a_3, q_3)}{\rightarrow} \cdots$$ (3)

and $q_i = q_f$ and $x_i \geq \bot$ for infinitely many $i \in \mathbb{N}$. By (3) and by definition of $B \times S_\bot$, we have $(q_i, a_i, q_{i+1}) \in \delta$ and $x_i \overset{a_i}{\rightarrow} x_{i+1}$ for every $i \in \mathbb{N}$. Therefore $a_1a_2 \cdots \in L(B) \cap \omega\text{-Traces}(x_0)$.

\hfill $\blacksquare$
