# Searching

## Definition (Search Problem)

**Input:** a sequence or set  $A$  of  $n$  elements (objects)  $\in \mathcal{A}$ , and an element  $x \in \mathcal{A}$ .

**Output:** The (smallest) index  $i \in \{1, \dots, n\}$  with  $x = A[i]$ , or NIL, if  $x \notin A$ .

```
SeqSearch (A: Array [1..n], x: Element) : Integer {  
    for i from 1 to n do {  
        if x = A[i] then return i;  
    }  
    return NIL;  
}
```

# Time Complexity of SeqSearch

```
SeqSearch (A: Array [1..n], x: Element) : Integer {  
  for i from 1 to n do {  
    if x = A[i] then return i;  
  }  
  return NIL;  
}
```

→ count number of comparisons

## Worst Case:

- we have to compare every  $A[i]$  with  $x \Rightarrow n$  comparisons
- occurs if  $A[n]=x$  or if  $x \notin A$

## Time Complexity of SeqSearch (2)

### Average Case:

- simplifying assumption: no duplicate elements
- $p :=$  probability that  $x = A[i]$   
(assumption:  $p$  independent of  $i$ )
- expected number of comparisons:

$$\bar{C}(n) = \sum_{i=1}^n pi + (1 - np)n = \frac{pn(n+1)}{2} + (1 - np)n$$

- assume that  $x$  occurs in  $A$ , thus  $p = \frac{1}{n}$ , then:

$$\bar{C}(n) = \frac{n(n+1)}{2n} + 0n = \frac{n+1}{2}$$

(on average, we have to search through half of the array)

## Searching – Divide and Conquer?

Will a divide-and-conquer approach work?

```
DQSearch(A: Array[p..r], x: Integer) : Integer {  
  if p=r  
  then {  
    if x=A[p] then return p  
    else return NIL;  
  }  
  else {  
    m := floor((p+r)/2);  
    q := DQSearch(A[p,m], x);  
    if q = NIL  
    then return DQSearch(A[m+1,r], x)  
    else return q;  
  }  
}
```

# Binary Search on Sorted Lists

Divide-and-conquer approach only works, if the array is sorted:

```
BinarySearch (A: Array[p..r], x: Integer) : Integer {  
  if p=r  
  then {  
    if x=A[p] then return p  
    else return NIL;  
  }  
  else {  
    m := floor((p+r)/2);  
    if x <= A[m]  
    then return BinarySearch(A[p..m], x)  
    else return BinarySearch(A[m+1..r], x)  
    end if;  
  }  
}
```

# Time Complexity of BinarySearch

Number of comparisons on an array with  $n$  elements:

- similar to divide-and-conquer:  $\log n$  subsequent recursive calls
- one comparison per call plus comparison with final element  
 $\rightsquigarrow 1 + \log n$
- homework: formulate as recurrence

## Discussion:

- What happens if we have to insert/delete elements in our sequence?  
 $\Rightarrow$  re-sorting of the sequence required  
 $\Rightarrow O(n \log n)$  effort
- therefore: Searching strongly dependent on choice of appropriate data structures for inserting and deleting elements!

# Binary Search Trees

An (**internal**) **binary search tree** stores the elements in a binary tree. Each tree-node corresponds to an element. All elements in the left sub-tree of a node  $v$  have a smaller key-value than  $\text{key}[v]$  and elements in the right sub-tree have a larger-key value. we assume that all key-values are different.

(**External** Search Trees store objects only at leaf-vertices)

Examples:

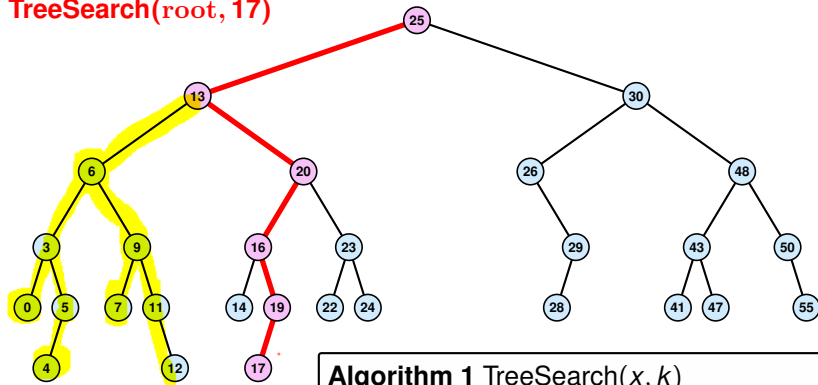

# Binary Search Trees

We consider the following operations on binary search trees. Note that this is a super-set of the dictionary-operations.

- $T.\text{insert}(x)$
- $T.\text{delete}(x)$
- $T.\text{search}(k)$
- $T.\text{successor}(x)$
- $T.\text{predecessor}(x)$
- $T.\text{minimum}()$
- $T.\text{maximum}()$

# Binary Search Trees: Searching

**TreeSearch**(root, 17)

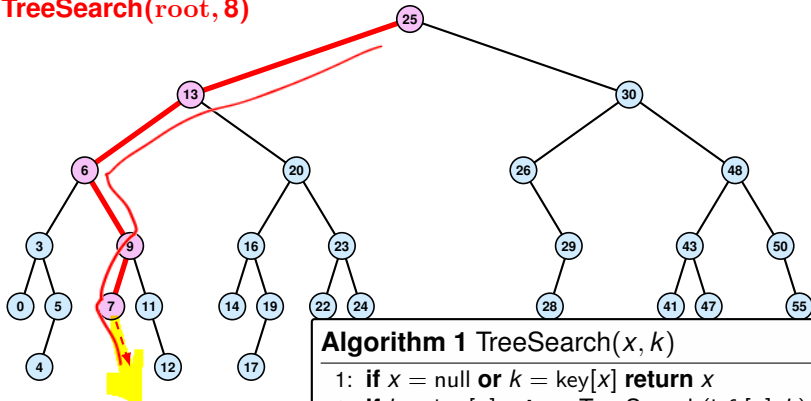

## Algorithm 1 TreeSearch( $x, k$ )

- 1: if  $x = \text{null}$  or  $k = \text{key}[x]$  return  $x$
- 2: if  $k < \text{key}[x]$  return TreeSearch(left[ $x$ ],  $k$ )
- 3: else return TreeSearch(right[ $x$ ],  $k$ )

# Binary Search Trees: Searching

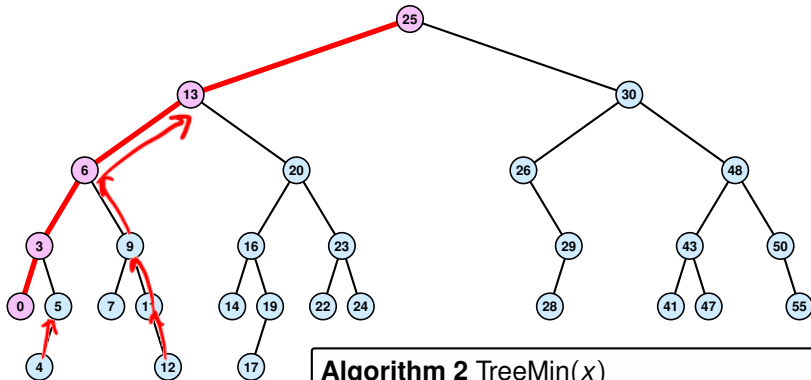

TreeSearch(root, 8)

**Algorithm 1** TreeSearch( $x, k$ )

- 1: **if**  $x = \text{null}$  **or**  $k = \text{key}[x]$  **return**  $x$
- 2: **if**  $k < \text{key}[x]$  **return** TreeSearch(left[ $x$ ],  $k$ )
- 3: **else return** TreeSearch(right[ $x$ ],  $k$ )

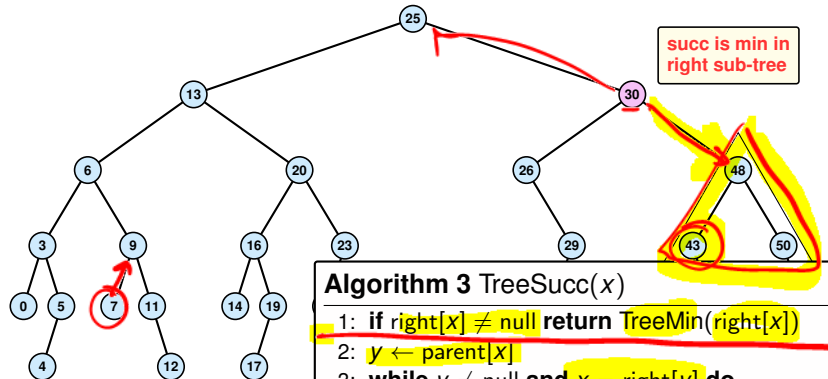

# Binary Search Trees: Minimum

## Algorithm 2 TreeMin( $x$ )

- 1: if  $x = \text{null}$  or  $\text{left}[x] = \text{null}$  return  $x$
- 2: return  $\text{TreeMin}(\text{left}[x])$

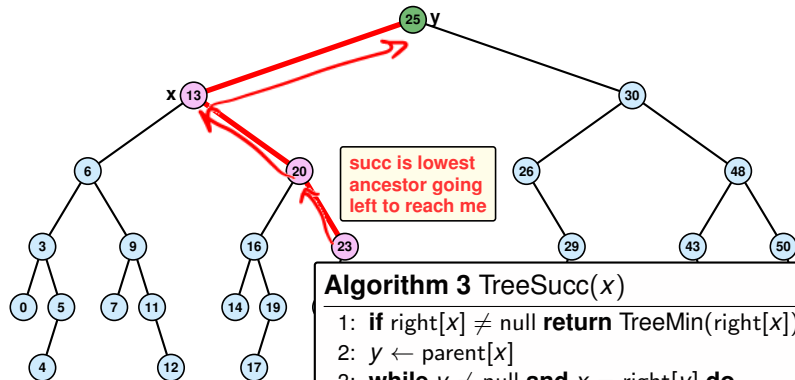

# Binary Search Trees: Successor

## Algorithm 3 TreeSucc(x)

- 1: if  $\text{right}[x] \neq \text{null}$  return  $\text{TreeMin}(\text{right}[x])$
- 2:  $y \leftarrow \text{parent}[x]$
- 3: while  $y \neq \text{null}$  and  $x = \text{right}[y]$  do
- 4:      $x \leftarrow y$ ;  $y \leftarrow \text{parent}[x]$
- 5: return  $y$ ;

# Binary Search Trees: Successor

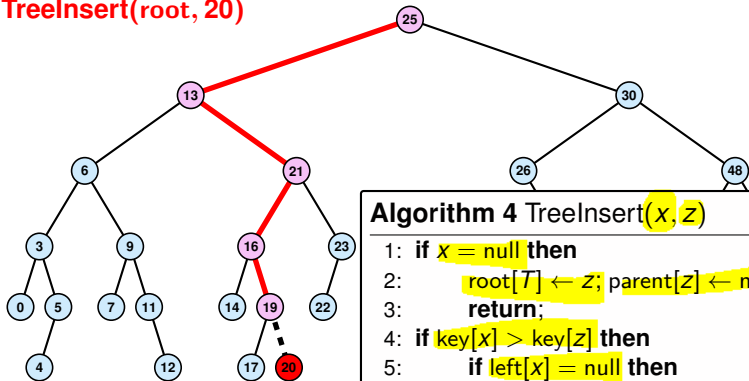

## Algorithm 3 TreeSucc( $x$ )

- 1: **if**  $\text{right}[x] \neq \text{null}$  **return**  $\text{TreeMin}(\text{right}[x])$
- 2:  $y \leftarrow \text{parent}[x]$
- 3: **while**  $y \neq \text{null}$  **and**  $x = \text{right}[y]$  **do**
- 4:      $x \leftarrow y; y \leftarrow \text{parent}[x]$
- 5: **return**  $y$ ;

# Binary Search Trees: Insert

Insert element **not** in the tree.

**TreeInsert**(root, 20)

Search for  $z$ . At some point the search stops at a null-pointer. This is the place to insert  $z$ .

## Algorithm 4 TreeInsert( $x, z$ )

- 1: if  $x = \text{null}$  then
- 2:      $\text{root}[T] \leftarrow z$ ;  $\text{parent}[z] \leftarrow \text{null}$ ;
- 3:     return;
- 4: if  $\text{key}[x] > \text{key}[z]$  then
- 5:     if  $\text{left}[x] = \text{null}$  then
- 6:          $\text{left}[x] \leftarrow z$ ;  $\text{parent}[z] \leftarrow x$ ;
- 7:     else TreeInsert( $\text{left}[x], z$ );
- 8: else
- 9:     if  $\text{right}[x] = \text{null}$  then
- 10:          $\text{right}[x] \leftarrow z$ ;  $\text{parent}[z] \leftarrow x$ ;
- 11:     else TreeInsert( $\text{right}[x], z$ );

# Binary Search Trees: Delete

## Case 1:

Element does not have any children

- Simply go to the parent and set the corresponding pointer to null.

# Binary Search Trees: Delete

## Case 2:

Element has exactly one child

- Splice the element out of the tree by connecting its parent to its successor.

# Binary Search Trees: Delete

## Case 3:

Element has two children

- Find the successor of the element
- Splice successor out of the tree
- Replace content of element by content of successor

# Binary Search Trees: Delete

## Algorithm 5 TreeDelete( $z$ )

```

1: if left[z] = null or right[z] = null
2:   then y ← z else y ← TreeSucc(z);
3: if left[y] ≠ null
4:   then x ← left[y] else x ← right[y];
5: if x ≠ null then parent[x] ← parent[y];
6: if parent[y] = null then
7:   root[T] ← x
8: else
9:   if y = left[parent[y]] then
10:    left[parent[y]] ← x
11:   else
12:    right[parent[y]] ← x
13: if y ≠ z then copy y-data to z
  
```

select  $y$  to splice out

$x$  is child of  $y$  (or null)  
parent[ $x$ ] is correct

} fix pointer to  $x$

$key[x] \leftarrow key[y]$

# Balanced Binary Search Trees

All operations on a binary search tree can be performed in time  $\mathcal{O}(h)$ , where  $h$  denotes the height of the tree.

However the height of the tree may become as large as  $\Theta(n)$ .

## Balanced Binary Search Trees

With each insert- and delete-operation perform **local** adjustments to guarantee a height of  $\mathcal{O}(\log n)$ .

AVL-trees, Red-black trees, Scapegoat trees, 2-3 trees, B-trees, AA trees, Treaps

similar: SPLAY trees.
